Approximate Bisimulation Relations for Constrained Linear Systems

Abstract
In this paper, we define the notion of approximate bisimulation relation between two systems, extending the well established exact bisimulation relations for discrete and continuous systems. Exact bisimulation requires that the observations of two systems are and remain identical, approximate bisimulation allows the observation to be different provided they are and remain arbitrarily close. Approximate bisimulation relations are conveniently defined as level sets of a function called bisimulation function. For the class of linear systems with constrained initial states and constrained inputs, we develop effective characterizations for bisimulation functions that can be interpreted in terms of linear matrix inequalities, set inclusion and games. We derive a computationally effective algorithm to evaluate the precision of the approximate bisimulation between a constrained linear system and its projection. This algorithm has been implemented in a MATLAB toolbox: MATISSE. Two examples of use of the toolbox in the context of safety verification are shown.

APPROXIMATE BISIMULATION RELATIONS
FOR CONSTRAINED LINEAR SYSTEMS

ANTOINE GIRARD AND GEORGE J. PAPPAS

Abstract. In this paper, we define the notion of approximate bisimulation relation between two systems, extending the well established exact bisimulation relations for discrete and continuous systems. Exact bisimulation requires that the observations of two systems are and remain identical, approximate bisimulation allows the observation to be different provided they are and remain arbitrarily close. Approximate bisimulation relations are conveniently defined as level sets of a function called bisimulation function. For the class of linear systems with constrained initial states and constrained inputs, we develop effective characterizations for bisimulation functions that can be interpreted in terms of linear matrix inequalities, set inclusion and games. We derive a computationally effective algorithm to evaluate the precision of the approximate bisimulation between a constrained linear system and its projection. This algorithm has been implemented in a MATLAB toolbox: MATISSE. Two examples of use of the toolbox in the context of safety verification are shown.

1. Introduction

Well established notions of system refinement and equivalence for discrete systems such as language inclusion, simulation and bisimulation relations have been shown useful to reduce the complexity of formal verification [CGP00]. Much more recently, the notions of simulation and bisimulation relations have been extended to continuous and hybrid state spaces resulting in new equivalence notions for nondeterministic continuous [Pap03, TP04, vdS04] and hybrid systems [HTP05, JvdS04, PvdSB04]. These abstraction concepts are all exact, requiring external behaviors of two systems to be identical. Approximate relationships which do allow for the possibility of error, will certainly allow for more dramatic system compression while providing more robust relationships between systems. An approach based on approximate versions of simulation and bisimulation relations seems promising and this idea has been explored recently for quantitative [dAFS04], stochastic [DGJP04, vBMOW03] and metric [GP05c] transition systems.

In [GP05c], we developed an approximation framework which applies for both discrete and continuous metric transition systems. We defined an approximate version of bisimulation relations based on a metric on the set of observation. While, exact bisimulation requires that the observations of two systems are and remain identical, approximate bisimulation allows the observation to be different provided they are and remain arbitrarily close (i.e. the distance between the observations is and remains bounded by the precision of the approximate bisimulation). Approximate bisimulation relations can be characterized as level sets of a function called bisimulation functions. A bisimulation function is a function bounding the distance between the observations of two systems and non-increasing under their parallel evolutions. This Lyapunov-like property allows to design computationally effective methods for the computation of bisimulation functions. Computational approaches have been

1
developed for metric transition systems derived from constrained linear dynamical systems [GP05a] and nonlinear (but deterministic) dynamical systems [GP05b].

This line of research has been motivated by the algorithmic verification of hybrid systems. The significant progress in the formal verification of discrete systems [BCM+90], has inspired a plethora of sophisticated methods for safety verification of continuous and hybrid systems. The approaches range from discrete and predicate abstraction methods [AHP00, ADI02, TK02], to reachability computations [ABDM00, ADG03, CK99, KV00, MT00, Gir05], to Lyapunov-like barriers [PJ04]. However, progress on continuous (and thus hybrid) systems has been limited to systems of small continuous dimension, motivating research on model reduction [HK04], and projection based methods [AD04] for safety verification. In [GP05a, GP05b], we showed that our approximation framework could be used to reduce significantly the complexity of algorithmic verification of continuous systems allowing to consider dynamics of larger dimension.

In this paper, we improve and extend our work presented in [GP05a] for the computation of bisimulation functions for a class of linear systems with constrained initial states and constrained inputs. We develop a characterization of bisimulation functions based on Lyapunov-like differential inequalities. We show that for a specific class of bisimulation functions based on quadratic forms these inequalities can be interpreted in terms of linear matrix inequalities, set inclusion and optimal values of static games. We derive an efficient algorithm to evaluate the precision of the approximate bisimulation between a constrained linear system and its projection. This algorithm has been implemented in a MATLAB toolbox: MATISSE (Metrics for Approximate TransItion Systems Simulation and Equivalence [GJP05]) available for download.

Compared to other approximation frameworks for linear systems such as traditional model reduction techniques [ASG00, BDG96, HK04], the reduction problem we consider is quite different and much more natural for safety verification for the following reasons. First, the systems we consider have constrained inputs which are internal (and hence they should be thought of as internal disturbances). The fidelity reproduction of the input-output mapping is therefore not our main concern. Second, we do not assume that the systems are initially at the equilibrium: contrarily to the model reduction framework, the transient dynamics of the systems are not ignored during the approximation process. From the point of view of verification, the transient phase and the asymptotic phase of a trajectory are of equal importance. In fact, the quality of the approximation may critically depend on initial set of states. Finally, since our research has been motivated by the algorithmic verification of continuous and hybrid systems, the error bounds we compute are based on the $L^\infty$ norm which is the only norm which makes sense for safety verification. In comparison, in [ASG00, BDG96], the error bounds stand for the $L^2$ norm; in [HK04] the error bound is valid only on a time interval of finite length. We conclude this paper by illustrating this point in the context of safety verification for constrained linear systems.

2. Approximation of transition systems

2.1. Metric transition systems. The theory has been developed in [GP05c] within the framework of metric transition systems. In this section, we summarize the main results. Metric transition systems can be seen as graphs (possibly with an infinite number of states and transitions) whose set of states and set of observations are metric spaces.

Definition 2.1 (Metric transition system). A (labeled) transition system with observations is a tuple $T = (Q, \Sigma, \rightarrow, Q^0, \Pi, \langle \cdot \rangle)$ that consists of:

- a (possibly infinite) set $Q$ of states,
- a (possibly infinite) set $\Sigma$ of labels,
- a transition relation $\rightarrow \subseteq Q \times \Sigma \times Q$,
- a (possibly infinite) set $Q^0 \subseteq Q$ of initial states,
- a (possibly infinite) set $\Pi$ of observations,
- an observation map $\langle \cdot \rangle : Q \rightarrow \Pi$.

If $(Q, d_Q)$ and $(\Pi, d_\Pi)$ are metric spaces, then $T$ is called a metric transition system. The set of metric transition systems associated to a set of labels $\Sigma$ and a set of observations $\Pi$ is denoted $T_M(\Sigma, \Pi)$.

A transition $(q, \sigma, q') \in \rightarrow$ will be denoted $q \xrightarrow{\sigma} q'$. We assume that the systems we consider are non-blocking so that for all $q \in Q$, there exists at least one transition $q \xrightarrow{\sigma} q'$ of $T$. For all labels $\sigma \in \Sigma$, the $\sigma$-successor is defined as the set valued map given by

$$\forall q \in Q, \operatorname{Post}^\sigma(q) = \left\{ q' \in Q \mid q \xrightarrow{\sigma} q' \right\}.$$ 

We denote with $\operatorname{Supp}(\operatorname{Post}^\sigma)$ the support of the $\sigma$-successor which is the subset of elements $q \in Q$ such that $\operatorname{Post}^\sigma(q)$ is not empty.

**Assumption 2.2.** The metric transition systems we consider satisfy the following properties:

1. the set of initial values $Q_0$ is a compact subset of $Q$,
2. for all $\sigma \in \Sigma$, for all $q \in \operatorname{Supp}(\operatorname{Post}^\sigma)$, $\operatorname{Post}^\sigma(q)$ is a compact subset of $Q$.

A state trajectory of $T$ is an infinite sequence of transitions,

$$q^0 \xrightarrow{\sigma^0} q^1 \xrightarrow{\sigma^1} q^2 \xrightarrow{\sigma^2} \ldots,$$

where $q^0 \in Q^0$.

An external trajectory is a sequence of elements of $\Pi \times \Sigma$ of the form $\pi^0 \xrightarrow{\sigma^0} \pi^1 \xrightarrow{\sigma^1} \pi^2 \xrightarrow{\sigma^2} \ldots$. An external trajectory is accepted by transition system $T$ if there exists a state trajectory of $T$, such that for all $i \in \mathbb{N}$, $\pi^i = (\langle q^i \rangle)$. The set of external trajectories accepted by transition system $T$ is called the language of $T$, and is denoted by $L(T)$. The reachable set of $T$ is the subset of $\Pi$ defined by:

$$\operatorname{Reach}(T) = \left\{ \pi \in \Pi \mid \exists \{ \pi^i \xrightarrow{\sigma^i} \pi^{i+1} \}_{i \in \mathbb{N}} \in L(T), \exists j \in \mathbb{N}, \pi^j = \pi \right\}.$$ 

An important problem for transition systems is the safety verification problem which asks whether the intersection of $\operatorname{Reach}(T)$ with an unsafe set $\Pi_U \subseteq \Pi$ is empty or not.

### 2.2. Approximate bisimulation relations

Let $T_1 = (Q_1, \Sigma_1, \rightarrow_1, Q^0_1, \Pi_1, \langle \cdot \rangle_{11})$ and $T_2 = (Q_2, \Sigma_2, \rightarrow_2, Q^0_2, \Pi_2, \langle \cdot \rangle_{12})$ be two metric transition systems with the same set of labels ($\Sigma_1 = \Sigma_2 = \Sigma$) and the same set of observations ($\Pi_1 = \Pi_2 = \Pi$) (i.e. $T_1$ and $T_2$ are elements of $T_M(\Sigma, \Pi)$).

The notion of approximate bisimulation relation is obtained from exact bisimulation relation [CGP00] by relaxation of the observational equivalence constraint. Instead of requiring that the observations of the two systems are and remain the same, we require that they are and remain arbitrarily close.

**Definition 2.3** (Approximate bisimulation). Let $T_1, T_2 \in T_M(\Sigma, \Pi)$. A relation $\mathcal{R}_\delta \subseteq Q_1 \times Q_2$ is called a $\delta$-approximate bisimulation relation between $T_1$ and $T_2$ if for all $(q_1, q_2) \in \mathcal{R}_\delta$:

1. $d_\Pi((\langle q_1 \rangle)_{11}, (\langle q_2 \rangle)_{12}) \leq \delta$,
2. for all $q_1 \xrightarrow{\sigma_1} q'_1$, there exists $q_2 \xrightarrow{\sigma_2} q'_2$ such that $(q'_1, q'_2) \in \mathcal{R}_\delta$, 

where $\delta > 0$.
Before we are able to give our main results, we need to prove the following Lemma:

Definition 2.4. Transition systems $T_1$ and $T_2$ are approximately bisimilar with precision $\delta$ (noted $T_1 \sim_\delta T_2$), if there exists $\mathcal{R}_\delta$, a $\delta$-approximate bisimulation relation between $T_1$ and $T_2$ such that for all $q_1 \in Q^1_T$, there exists $q_2 \in Q^2_T$ such that $(q_1, q_2) \in \mathcal{R}_\delta$ and conversely.

The distance between the languages of two approximately bisimilar transition systems is bounded by the precision of the approximate bisimulation relation:

Theorem 2.5 (adapted from [GP05c]). If $T_1 \sim_\delta T_2$ then for all external trajectory accepted by $T_1$ (respectively $T_2$), $\pi^0_1 \xrightarrow{\sigma^0} \pi^1_1 \xrightarrow{\sigma^1} \pi^2_1 \xrightarrow{\sigma^2} \ldots$ there exists an external trajectory accepted by $T_2$ (respectively $T_1$), with the same sequence of labels, $\pi^0_2 \xrightarrow{\sigma^0} \pi^1_2 \xrightarrow{\sigma^1} \pi^2_2 \xrightarrow{\sigma^2} \ldots$ such that for all $i \in \mathbb{N}$, $d_\Pi(\pi^1_i, \pi^2_i) \leq \delta$.

Proof. If $T_1 \sim_\delta T_2$ then there exists a $\delta$-approximate bisimulation relation $\mathcal{R}_\delta$ as in Definition 2.4. Let $\pi^0_1 \xrightarrow{\sigma^0} \pi^1_1 \xrightarrow{\sigma^1} \pi^2_1 \xrightarrow{\sigma^2} \ldots$ be an external trajectory accepted by $T_1$. Then, there exists a state trajectory of $T_1$, $q^0_1 \xrightarrow{\sigma^0} q^1_1 \xrightarrow{\sigma^1} q^2_1 \xrightarrow{\sigma^2} \ldots$ such that for all $i \in \mathbb{N}$, $(\langle q^1_i \rangle)_1 = \pi^1_i$. From Definition 2.4, there exists $q^0_2 \in Q^2_T$ such that $(\langle q^0_1, q^0_2 \rangle) \in \mathcal{R}_\delta$. By induction, it is easy to see that there exists a state trajectory of $T_2$ starting from $q^0_2$ and with the sequence of labels: $\pi^0_2 \xrightarrow{\sigma^0} \pi^1_2 \xrightarrow{\sigma^1} \pi^2_2 \xrightarrow{\sigma^2} \ldots$ and such that for all $i \in \mathbb{N}$, $(q^1_i, q^2_i) \in \mathcal{R}_\delta$. Then, the external trajectory, $\pi^0_2 \xrightarrow{\sigma^0} \pi^1_2 \xrightarrow{\sigma^1} \pi^2_2 \xrightarrow{\sigma^2} \ldots$, where $\pi^1_i = (\langle q^1_i \rangle)_1$, $(\langle q^2_i \rangle)_2$ for all $i \in \mathbb{N}$, is accepted by $T_2$ and, for all $i \in \mathbb{N}$, $d_\Pi(\pi^1_i, \pi^2_i) = d_\Pi((\langle q^1_i \rangle)_1, (\langle q^2_i \rangle)_2) \leq \delta$. \qed

From Theorem 2.5, it is straightforward that if $T_1 \sim_\delta T_2$ then the distance between the reachable sets of $T_1$ and $T_2$ is bounded by the precision $\delta$. In the context of safety verification, this approximation property is of great use since

$$\text{Reach}(T_2) \cap N(\Pi_U, \delta) = \emptyset \implies \text{Reach}(T_1) \cap \Pi_U = \emptyset$$

where $N(\pi, \delta)$ denotes the $\delta$ neighborhood of $\pi \in \Pi$.

2.3. Bisimulation functions. The problem of system approximation can be handled more practically by a dual approach to the one based on approximate bisimulation relations. It is based on a class of functions called bisimulation functions. A bisimulation function between $T_1$ and $T_2$ is a positive function defined on $Q_1 \times Q_2$, bounding the distance between the observations associated to the couple $(q_1, q_2)$ and non increasing under the dynamics of the systems.

Definition 2.6 (Bisimulation function). A function $V : Q_1 \times Q_2 \to \mathbb{R}^+ \cup \{+\infty\}$ is called a bisimulation function between $T_1$ and $T_2$ if its level sets are closed, and for all $(q_1, q_2) \in Q_1 \times Q_2$:

$$V(q_1, q_2) \geq \max \left( d_\Pi((\langle q_1 \rangle)_1, (\langle q_2 \rangle)_2), \sup_{q_1 \xrightarrow{\sigma} q'_1, q_2 \xrightarrow{\sigma} q'_2} V(q'_1, q'_2), \sup_{q_2 \xrightarrow{\sigma} q'_2, q_1 \xrightarrow{\sigma} q'_1} V(q'_1, q'_2) \right).$$

Before we are able to give our main results, we need to prove the following Lemma:
Lemma 2.7. Let \( V : Q_1 \times Q_2 \rightarrow \mathbb{R}^+ \cup \{+\infty\} \) be a function with closed level sets. Let \( C_2 \) be a compact subset of \( Q_2 \), then

\[
\forall q_1 \in Q_1, \exists q_2 \in C_2, \text{ such that } V(q_1, q_2) = \inf_{q_2 \in C_2} V(q_1, q_2).
\]

Proof. Let \( q_1 \in Q_1 \), and \( \delta = \inf_{q_2 \in C_2} V(q_1, q_2) \). Let \( \{\varepsilon_i\}_{i \in \mathbb{N}} \) be a decreasing sequence of real numbers converging to 0. Then, for all \( i \in \mathbb{N} \), there exists \( q_2^i \in C_2 \) such that \( V(q_1, q_2^i) \leq \delta + \varepsilon_i \). Since \( C_2 \) is compact, there exists a subsequence of \( \{q_2^i\}_{i \in \mathbb{N}} \) which we will also note \( \{q_2^{i_n}\}_{n \in \mathbb{N}} \) and which converges to a limit \( q_2 \in C_2 \). Let \( \varepsilon > 0 \), there exists \( n \in \mathbb{N} \), such that for all \( i \geq n \), \( \varepsilon_i \leq \varepsilon \). Then, for all \( i \geq n \), \( V(q_1, q_2^i) \leq \delta + \varepsilon \). Since the levels sets of \( V \) are closed subsets of \( Q_1 \times Q_2 \), it follows that \( V(q_1, q_2) \leq \delta + \varepsilon \). Finally, since this holds for all \( \varepsilon > 0 \), \( V(q_1, q_2) \leq \delta \).

The duality of the approach using approximate bisimulation relations and the approach using bisimulation functions is captured by the following result:

Theorem 2.8. [GP05c] Let \( V \) be a bisimulation function between \( T_1 \) and \( T_2 \). Then for all \( \delta \geq 0 \),

\[
\mathcal{R}_\delta = \{(q_1, q_2) \in Q_1 \times Q_2 | V(q_1, q_2) \leq \delta\}
\]

is a \( \delta \)-approximate bisimulation relation between \( T_1 \) and \( T_2 \).

Proof. It is clear that \( \mathcal{R}_\delta \) satisfies the first property of Definition 2.3. Let \( (q_1, q_2) \in \mathcal{R}_\delta \), let \( q_1 \sim T_1 q_1' \), from the regularity assumptions we made on \( T_2 \), the set \( \text{Post}_2(q_2) \) is compact and therefore from Lemma 2.7, there exists \( q_2' \sim T_2 q_2' \) such that

\[
V(q_1', q_2') = \inf_{q_2' \sim T_2 q_2'} V(q_1', q_2') \leq \sup_{q_1 \sim T_1 q_1'} \inf_{q_2' \sim T_2 q_2'} V(q_1', q_2') \leq V(q_1, q_2) \leq \delta.
\]

Then, \( (q_1', q_2') \) is an element of \( \mathcal{R}_\delta \) and the second property as well as the third property (using symmetrical arguments) of Definition 2.3 hold. \( \mathcal{R}_\delta \) is consequently a \( \delta \)-approximate bisimulation relation between \( T_1 \) and \( T_2 \).

Let us remark that particularly the zero set of a bisimulation function is an exact bisimulation relation. From Theorem 2.5, it is clear that for good approximation results it is necessary to have a tight evaluation of the precision \( \delta \) for which \( T_1 \sim \delta T_2 \). Given a bisimulation function between \( T_1 \) and \( T_2 \), this can be done by solving a game.

Theorem 2.9 (adapted from [GP05c]). Let \( V \) be a bisimulation function between \( T_1 \) and \( T_2 \) and

\[
(2.1) \quad \delta = \max \left( \sup_{q_1 \in Q_1^0} \inf_{q_2 \in Q_2^0 \setminus Q_1^0} V(q_1, q_2), \sup_{q_2 \in Q_2^0} \inf_{q_1 \in Q_1^0} V(q_1, q_2) \right).
\]

If the value of \( \delta \) is finite, then \( T_1 \sim \delta T_2 \).

Proof. Let \( q_1 \in Q_1^0 \), from the regularity assumptions we made on \( T_2 \), the set \( Q_2^0 \) is compact and therefore from Lemma 2.7, there exists \( q_2 \in Q_2^0 \) such that

\[
V(q_1, q_2) = \inf_{q_2 \in Q_2^0} V(q_1, q_2) \leq \sup_{q_1 \in Q_1^0} \inf_{q_2 \in Q_2^0} V(q_1, q_2) = \delta.
\]

Hence, for all \( q_1 \in Q_1^0 \), there exists \( q_2 \in Q_2^0 \) such that \( (q_1, q_2) \) is in \( \mathcal{R}_\delta \), the \( \delta \)-approximate bisimulation relation of \( T_1 \) by \( T_2 \) defined in Theorem 2.8. Similarly, we can show that for all \( q_2 \in Q_2^0 \), there exists \( q_1 \in Q_1^0 \) such that \( (q_1, q_2) \) is in \( \mathcal{R}_\delta \). Then, \( T_1 \sim \delta T_2 \).
Let us remark that for any $\delta' \geq \delta$, we also have $T_1 \sim_{\delta'} T_2$. It appears that one of the challenge of this theory of system approximation is the computation of bisimulation functions. The purpose of this paper is to address this problem for the class of continuous-time constrained linear systems.

3. Bisimulation functions for constrained linear systems

Let us consider the following class of linear systems with constrained inputs and constrained initial states:

$$\Delta_i : \begin{cases} \dot{x}_i(t) &= A_ix_i(t) + B_iu_i(t), x_i(t) \in \mathbb{R}^{m_i}, \ u_i(t) \in U_i, \ x_i(0) \in I_i, \ i = 1, 2 \end{cases}$$

where $I_i$ is a compact subset of $\mathbb{R}^{m_i}$ and $U_i$ is a convex compact subset of $\mathbb{R}^{m_i}$. One may want to think of $I_i$ and $U_i$ as bounded polytopes. The constrained inputs of systems $\Delta_1$ and $\Delta_2$ are to be understood as disturbances rather than control variables. In the spirit of [Pap03], the dynamical system $\Delta_i$ can be written as a non-deterministic metric transition system $T_{\Delta_i} = (Q_i, \Sigma_i, \rightarrow_i, Q_0^i, \Pi_i, \langle\cdot\rangle_i)$ where:

- The set of states is $Q_i = \mathbb{R}^{m_i}$,
- The set of labels is $\Sigma_i = \mathbb{R}^+$,
- The transition relation $\rightarrow_i \subseteq Q_i \times \Sigma_i \times Q_i$ is given by $x \xrightarrow{\cdot} x'$ if and only if there exists a locally measurable function $u(.)$ such that

$$(\text{for all } s \in [0, t], \ u(s) \in U_i \text{ and } x' = e^{A_i t}x + \int_0^t e^{A_i(t-s)}B_iu(s)ds),$$

- The set of initial states is $Q_0^i = I_i$,
- The set of observations is $\Pi_i = \mathbb{R}^p$,
- The observation map is given by $\langle x \rangle_i = C_i x$.

The sets of states and observations are equipped with the traditional Euclidean distance. Note that $T_{\Delta_1}$ and $T_{\Delta_2}$ are elements of the set of metric transition systems $T_M(\mathbb{R}^+, \mathbb{R}^p)$. We can check that they satisfy Assumption 2.2 (see for instance [Aub01]). Let us introduce the following notations:

$$A = \begin{bmatrix} A_1 & 0 \\ 0 & A_2 \end{bmatrix}, B_1 = \begin{bmatrix} B_1 \\ 0 \end{bmatrix}, B_2 = \begin{bmatrix} 0 \\ B_2 \end{bmatrix}, C = \begin{bmatrix} C_1 & -C_2 \end{bmatrix} \text{ and } x = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}.$$ 

For such metric transition systems, Definition 2.6 is not a very convenient way to characterize bisimulation functions. In this section, we derive a characterization of bisimulation functions based on Lyapunov-like differential inequalities. The different characterizations of bisimulation functions given in this paper are derived from the following result:

**Proposition 3.1.** Let $f : \mathbb{R}^{m_1} \times \mathbb{R}^{m_2} \rightarrow \mathbb{R}^+$ be a $C^1$ function and $\mathcal{H}$ a subspace of $\mathbb{R}^{m_1} \times \mathbb{R}^{m_2}$ such that for all $u_1 \in U_1$ there exists $u_2 \in U_2$ satisfying $f(u_1, u_2) \in \mathcal{H}$. Let us assume that there exists $\eta \geq 0$, such that for all $(x_1, x_2)$ satisfying $f(x_1, x_2) \geq \eta$,

$$\sup_{u_1 \in U_1} \left( \inf_{u_2 \in U_2, (u_1, u_2) \in \mathcal{H}} \nabla f(x)(Ax + B_1u_1 + B_2u_2) \right) \leq 0.$$ 

Then, for all $(x_1, x_2) \in \mathbb{R}^{m_1} \times \mathbb{R}^{m_2}$, for all $x_1 \xrightarrow{\cdot} x'_1$, there exists $x_2 \xrightarrow{\cdot} x'_2$ such that

$$f(x'_1, x'_2) \leq \max(f(x_1, x_2), \eta).$$

Moreover, there exist inputs $u_i(.)$ ($i = 1, 2$) leading $\Delta_i$ from $x_i$ to $x'_i$ at time $t$ and such that for all $s \in [0, t]$, $(u_1(s), u_2(s)) \in \mathcal{H}$. 

Let us remark that a symmetrical result holds when the maximization is done over \( U_2 \) and the minimization over \( U_1 \). The proof of this proposition is quite technical and is therefore stated in appendix. In the following, based on Proposition 3.1, we will derive several characterizations for bisimulation functions. Particularly, for smooth bisimulation functions with finite values on \( \mathbb{R}^{n_1} \times \mathbb{R}^{n_2} \), we have:

**Theorem 3.2.** Let \( f : \mathbb{R}^{n_1} \times \mathbb{R}^{n_2} \to \mathbb{R}^+ \) be a \( C^1 \) function. If for all \( x \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2} \),

\[
(3.3) \quad f(x) \geq x^T C^T C x,
\]

\[
(3.4) \quad \sup_{u_1 \in U_1} \inf_{u_2 \in U_2} \nabla f(x)(A x + B_1 u_1 + B_2 u_2) \leq 0,
\]

\[
(3.5) \quad \sup_{u_2 \in U_2} \inf_{u_1 \in U_1} \nabla f(x)(A x + B_1 u_1 + B_2 u_2) \leq 0.
\]

Then, \( V(x_1, x_2) = \sqrt{f(x_1, x_2)} \) is a bisimulation function between \( T_{\Delta_1} \) and \( T_{\Delta_2} \).

**Proof.** Let \( (x_1, x_2) \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2} \), \( x_1 \xrightarrow{t} x_1' \). It follows from equation (3.4) and Proposition 3.1 (with \( H = \mathbb{R}^{n_1} \times \mathbb{R}^{n_2} \) and \( \eta = 0 \)) that there exists \( x_2 \xrightarrow{t} x_2' \) such that \( f(x_1', x_2') \leq f(x_1, x_2) \). Symmetrically, we can show from equation (3.5) that for all \( x_2 \xrightarrow{t} x_2' \), there exists \( x_1 \xrightarrow{t} x_1' \) such that \( f(x_1', x_2') \leq f(x_1, x_2) \). Together with equation (3.3), this allows to conclude that \( V(x_1, x_2) = \sqrt{f(x_1, x_2)} \) is a bisimulation function between \( T_{\Delta_1} \) and \( T_{\Delta_2} \). \( \square \)

**Remark 3.3.** There are similarities between the notions of bisimulation function and robust control Lyapunov function [FK96, LSW02] as well as some significant conceptual differences. Indeed, let us consider the input \( u_1 \) as a disturbance and the input \( u_2 \) as a control variable in equation (3.4). Then, the interpretation of this inequality is that for all disturbances there exists a control such that the bisimulation function does not increase during the evolution of the system. This means that the choice of \( u_2 \) can be made with the knowledge of \( u_1 \). In comparison, a robust control Lyapunov function requires that there exists a control \( u_2 \) such that for all disturbances \( u_1 \), the function decreases during the evolution of the system. Thus, it appears that robust control Lyapunov functions require stronger conditions than bisimulation functions.

**Example 3.4.** Let us consider the following three dimensional dynamical system \( \Delta_1 \) whose dynamics is given by:

\[
\begin{align*}
\dot{z}_1(t) &= -8z_1(t) + 7z_2(t) - 7z_3(t) + u_1(t) \\
\dot{z}_2(t) &= \quad 3z_1(t) + \quad z_2(t) + 4z_3(t) + u_2(t) \\
\dot{z}_3(t) &= \quad 2z_1(t) + \quad 2z_2(t) + 2z_3(t) - u_1(t) + u_2(t)
\end{align*}
\]

The system is observed through the output variable \( y_1(t) = z_1(t) \). The value of the inputs are constrained in the following way: \( u_1(t) \in [-1, 1] \), \( u_2(t) \in [0, 2] \). The set of initial states is the polytope \( I_1 \) defined by

\[
I_1 = \{ 6 \leq z_1(0) \leq 8, -2 \leq z_2(0) \leq -3, -1 \leq z_1(0) - z_2(0) + z_3(0) \leq 1 \}.
\]

As stated previously, we can derive from \( \Delta_1 \) a metric transition system \( T_{\Delta_1} \in T_M(\mathbb{R}^+, \mathbb{R}) \). We want to show that \( T_{\Delta_1} \) can be approximated by the metric transition system \( T_{\Delta_2} \in T_M(\mathbb{R}^+, \mathbb{R}) \) derived from the one dimensional dynamical system \( \Delta_2 \) whose dynamics is given by:

\[
\dot{x}(t) = -x(t) + v(t).
\]
is a bisimulation function between $T_{\Delta_1}$ and $T_{\Delta_2}$. Let us assume that both systems $\Delta_1$ and $\Delta_2$ are Lyapunov-like differential inequalities. For autonomous linear systems, it is well known that quadratic forms provide universal and computationally effective Lyapunov functions. Hence, it seems reasonable to search a bisimulation function of the form:

$$\forall (x_1, x_2) \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}, \ V(x_1, x_2) = \sqrt{x^T M x}.$$ 

Then, Theorem 3.2 becomes

$$\forall (x_1, x_2) \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}, \ V(x_1, x_2) = \sqrt{x^T M x}. $$
Proposition 4.1. If for all $x \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}$,
\begin{equation}
(4.2) \quad x^T C^T C x \geq 0,
\end{equation}
\begin{equation}
(4.3) \quad x^T M x + x^T A^T M x + 2 \sup_{u_1 \in U_1} \inf_{u_2 \in U_2} x^T M (B_1 u_1 + B_2 u_2) \leq 0,
\end{equation}
\begin{equation}
(4.4) \quad x^T M x + x^T A^T M x + 2 \sup_{u_2 \in U_2} \inf_{u_1 \in U_1} x^T M (B_1 u_1 + B_2 u_2) \leq 0.
\end{equation}
Then, $V(x_1, x_2) = \sqrt{x^T M x}$ is a bisimulation function between $T_{\Delta_1}$ and $T_{\Delta_2}$.

We can find equivalent conditions in terms of linear matrix inequalities and set equalities:

Theorem 4.2. Equations (4.2) (4.3) and (4.4) are equivalent to
\begin{equation}
(4.5) \quad M \succ C^T C,
\end{equation}
\begin{equation}
(4.6) \quad A^T M + M A \leq 0,
\end{equation}
\begin{equation}
(4.7) \quad \ker(M) + B_1 U_1 = \ker(M) - B_2 U_2.
\end{equation}
If equations (4.5), (4.6) and (4.7) hold then $V(x_1, x_2) = \sqrt{x^T M x}$ is a bisimulation function between $T_{\Delta_1}$ and $T_{\Delta_2}$.

Proof. First, equation (4.5) is equivalent to equation (4.2). Let us assume that equations (4.6) and (4.7) hold. Then, for all $u_1 \in U_1$, there exists $v \in \ker(M)$ and $u_2 \in U_2$ such that $B_1 u_1 = v - B_2 u_2$. Then,
\begin{equation}
\forall x \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}, \quad \sup_{u_1 \in U_1} \inf_{u_2 \in U_2} x^T M (B_1 u_1 + B_2 u_2) \leq 0.
\end{equation}
Similarly, for all $u_2 \in U_2$, there exists $v \in \ker(M)$ and $u_1 \in U_1$ such that $-B_2 u_2 = v + B_1 u_1$. Then,
\begin{equation}
\forall x \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}, \quad \sup_{u_2 \in U_2} \inf_{u_1 \in U_1} x^T M (B_1 u_1 + B_2 u_2) \leq 0.
\end{equation}
From the linear matrix inequality (4.6), it follows that equations (4.3) and (4.4) hold. Conversely, let us assume that equation (4.3) holds. Let $x \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}$, then
\begin{equation}
(4.8) \quad \forall \lambda > 0, \quad \lambda^2 (x^T A^T M x + x^T M A x) + 2 \lambda \sup_{u_1 \in U_1} \inf_{u_2 \in U_2} x^T M (B_1 u_1 + B_2 u_2) \leq 0.
\end{equation}
If $x^T A^T M x + x^T M A x > 0$, then for $\lambda$ sufficiently large, inequality (4.8) cannot hold. Necessarily, we have the linear matrix inequality (4.6). If
\begin{equation}
\sup_{u_1 \in U_1} \inf_{u_2 \in U_2} x^T M (B_1 u_1 + B_2 u_2) > 0
\end{equation}
then for $\lambda$ sufficiently small equation (4.8) cannot hold. Hence,
\begin{equation}
(4.9) \quad \forall x \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}, \quad \sup_{u_1 \in U_1} \inf_{u_2 \in U_2} x^T M (B_1 u_1 + B_2 u_2) \leq 0.
\end{equation}
Since $U_1$ and $U_2$ are compact and then bounded, we have
\begin{equation}
\sup_{u_1 \in U_1} \inf_{u_2 \in U_2} x^T M (B_1 u_1 + B_2 u_2) = \sup_{u_1 \in U_1} x^T M B_1 u_1 + \inf_{u_2 \in U_2} x^T M B_2 u_2
= \sup_{v \in MB_1 U_1} x^T v - \sup_{v \in MB_2 U_2} x^T v
= S_{MB_1 U_1}(x) - S_{-MB_2 U_2}(x)
\end{equation}
where $S_{M\overline{B}_1U_1}$ and $S_{-M\overline{B}_2U_2}$ denote the support functions of the sets $M\overline{B}_1U_1$ and $-M\overline{B}_2U_2$. Then, inequality (4.9) becomes
\begin{equation}
\forall x \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}, \quad S_{M\overline{B}_1U_1}(x) \leq S_{-M\overline{B}_2U_2}(x)
\end{equation}
which is equivalent to say, since $M\overline{B}_1U_1$ and $-M\overline{B}_2U_2$ are compact convex sets, that $M\overline{B}_1U_1$ is a subset of $-M\overline{B}_2U_2$. Then, for all $u_1 \in U_1$, there exists $u_2 \in U_2$ such that $M\overline{B}_1u_1 = -M\overline{B}_2u_2$ which means that $\overline{B}_1u_1 + \overline{B}_2u_2 \in \ker(M)$ which implies that $\overline{B}_1U_1 + \subset \ker(M) + \overline{B}_2U_2$. Similarly, we can show from equation (4.4) that $-\overline{B}_2U_2 \subset \ker(M) + \overline{B}_1U_1$. Hence, equation (4.7) also holds. \qed

Quadratic bisimulation functions are particularly useful for autonomous systems (i.e. $B_1 = 0$, $B_2 = 0$). Indeed, in that case, equation (4.7) is always satisfied. Then, the characterization of a bisimulation function between $T_{\Delta_1}$ and $T_{\Delta_2}$ reduces to a set of linear matrix inequalities. Moreover, for stable autonomous linear systems, we can show that a quadratic bisimulation function always exists.

**Proposition 4.3.** Let $\Delta_1$ and $\Delta_2$ be asymptotically stable autonomous linear systems, then there exists a bisimulation function of the form (4.1) between $T_{\Delta_1}$ and $T_{\Delta_2}$.

**Proof.** Linear matrix inequality (4.5) is equivalent to say that $M = C^TC + N$ where $N$ is a positive semi-definite symmetric matrix. Then, linear matrix inequality (4.6) becomes
\begin{equation}
A^TN + NA \leq -(A^TC^TC + C^TCN).
\end{equation}
Let us remark that $A^TC^TC + C^TCN$ is a symmetric matrix and then can be written as the difference between two positive semi-definite symmetric matrices $Q^+$ and $Q^-$: $A^TC^TC + C^TCN = Q^+ - Q^-$. Let us consider the Lyapunov equation
\begin{equation}
A^TN + NA = -Q^+.
\end{equation}
Since $\Delta_1$ and $\Delta_2$ are asymptotically stable, there exists a unique solution $N$ to this Lyapunov equation. This solution is positive semi-definite symmetric and clearly satisfies inequality (4.10). Therefore, for $M = C^TC + N$, $V(x_1, x_2) = \sqrt{x^TMx}$ is a bisimulation function between $T_{\Delta_1}$ and $T_{\Delta_2}$. \qed

**Corollary 4.4.** Let $\Delta_1$ and $\Delta_2$ be asymptotically stable autonomous linear systems, then $T_{\Delta_1}$ and $T_{\Delta_2}$ are approximately bisimilar.

**Proof.** The proof is straightforward from the fact that the game given by equation (2.1) has obviously a finite value since $I_1$ and $I_2$ are compact sets. \qed

Considering quadratic bisimulation functions for linear systems with inputs is actually quite restrictive. Indeed, the value of quadratic functions at $x = 0$ is always 0. Particularly, this means that if $\Delta_1$ and $\Delta_2$ start from 0, the outputs of both systems will be identical. Equivalently, this means that $\Delta_1$ and $\Delta_2$ have identical asymptotic behaviors and that only their transient behaviors can differ. Therefore, we need to consider more general classes of functions so that bisimulation functions exist even if $\Delta_1$ and $\Delta_2$ do not have identical asymptotic behaviors.
4.2. **Truncated quadratic bisimulation functions.** A natural extension of quadratic bisimulation functions is the class of truncated quadratic bisimulation functions:

\[
V(x_1, x_2) = \max(\sqrt{x^T M x}, \alpha).
\]

The choice of such a form is motivated by the following remark. Trajectories of stable constrained linear systems can be decomposed into two phases: the transient phase and the asymptotic phase. The initial states affect only the transient phase. Here, the term \(\sqrt{x^T M x}\) in \(V(x_1, x_2)\) can be interpreted as the error of approximation due to the transient phase. Then, the term \(\alpha\) accounts for the error of approximation due to the asymptotic phase and is thus independent of the initial states of the systems.

**Proposition 4.5.** If for all \(x \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}\),

\[
x^T M x \geq x^T C^T C x
\]

and for all \(x \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}\), such that \(x^T M x \geq \alpha^2\),

\[
x^T M A x + x^T A^T M x + 2 \sup_{u_1 \in U_1} \inf_{u_2 \in U_2} x^T M (B_1 u_1 + B_2 u_2) \leq 0,
\]

and

\[
x^T M A x + x^T A^T M x + 2 \sup_{u_2 \in U_2} \inf_{u_1 \in U_1} x^T M (B_1 u_1 + B_2 u_2) \leq 0.
\]

Then, \(V(x_1, x_2) = \max(\sqrt{x^T M x}, \alpha)\) is a bisimulation function between \(T_{\Delta_1}\) and \(T_{\Delta_2}\).

**Proof.** Let \(f(x) = x^T M x\), let \((x_1, x_2) \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}\). From equation (4.13) and Proposition 3.1 (with \(H = \mathbb{R}^{m_1} \times \mathbb{R}^{m_2}\) and \(\eta = \alpha^2\)), we have that for all \(x_1 \xrightarrow{t_1} x'_1\), there exists \(x_2 \xrightarrow{t_2} x'_2\) such that \(f(x'_1, x'_2) \leq \max(f(x_1, x_2), \alpha^2)\) which implies that \(V(x'_1, x'_2) \leq V(x_1, x_2)\). Similarly, from equation (4.14), we can show that for all \(x_2 \xrightarrow{t_2} x'_2\), there exists \(x_1 \xrightarrow{t_1} x'_1\) such that \(V(x'_1, x'_2) \leq V(x_1, x_2)\). Equation (4.12) allows to conclude that \(V(x_1, x_2)\) is a bisimulation function between \(T_{\Delta_1}\) and \(T_{\Delta_2}\). \(\square\)

A more effective characterization result can be given for truncated quadratic bisimulation functions.

**Theorem 4.6.** If there exists \(\lambda > 0\), such that

\[
M \geq C^T C,
\]

\[
A^T M + M A + 2 \lambda M \leq 0
\]

\[
\alpha \geq \frac{1}{\lambda} \sup_{x^T M x = 1} \left( \sup_{u_1 \in U_1} \inf_{u_2 \in U_2} x^T M (B_1 u_1 + B_2 u_2) \right),
\]

\[
\alpha \geq \frac{1}{\lambda} \sup_{x^T M x = 1} \left( \sup_{u_2 \in U_2} \inf_{u_1 \in U_1} x^T M (B_1 u_1 + B_2 u_2) \right).
\]

Then, the function \(V(x_1, x_2) = \max(\sqrt{x^T M x}, \alpha)\) is a bisimulation function between \(T_{\Delta_1}\) and \(T_{\Delta_2}\).

**Proof.** Equation (4.15) is equivalent to equation (4.12). Let \((x_1, x_2) \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}\) such that \(x^T M x \geq \alpha^2\). Then, equation (4.17) implies that

\[
\sup_{u_1 \in U_1} \inf_{u_2 \in U_2} x^T M (B_1 u_1 + B_2 u_2) \leq \lambda \alpha \sqrt{x^T M x}.
\]
Therefore,
\[ x^TA^TMx + x^TMAx + 2 \sup_{u_1 \in U_1, u_2 \in U_2} \inf_{\bar{u}_1 \in \bar{U}_1, \bar{u}_2 \in \bar{U}_2} x^TM(\overline{B}_1u_1 + \overline{B}_2u_2) \leq x^TA^TMx + x^TMAx + 2\lambda x^TMx. \]

Then, from equation (4.16)
\[ x^TA^TMx + x^TMAx + 2 \sup_{u_1 \in U_1, u_2 \in U_2} \inf_{\bar{u}_1 \in \bar{U}_1, \bar{u}_2 \in \bar{U}_2} x^TM((B_1u_1 + B_2u_2)) \leq -2\lambda x^TMx + 2\lambda \alpha \sqrt{x^TMx} \leq -2\lambda \sqrt{x^TMx}(\sqrt{x^TMx} - \alpha) \leq 0. \]

Thus, for all \( x \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2} \) such that \( x^TMx \geq \alpha^2 \), equation (4.13) holds. Similarly, from equations (4.16) and (4.18), we can show that equation (4.14) holds. Then, from Proposition 4.5, \( V(x_1, x_2) = \max(\sqrt{x^TMx}, \alpha) \) is a bisimulation function between \( T_{\Delta_1} \) and \( T_{\Delta_2} \).

**Example 4.7.** Let us consider that following systems:
\[ \Delta_1 : \begin{cases} \dot{x}_1(t) = -x_1(t) + u_1(t), & u_1(t) \in [-1, 1] \\ y_1(t) = x_1(t) \end{cases} \]
\[ \Delta_2 : \begin{cases} \dot{x}_2(t) = -x_2(t) \\ y_2(t) = x_2(t) \end{cases} \]

Let us define
\[ M = C^TC = \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix}. \]

Equation (4.15) holds. We can check that \( A^TM + MA = -2M \). Hence, equation (4.16) holds for \( \lambda = 1 \). Equation (4.17) becomes
\[ \alpha \geq \sup_{(x_1 - x_2)^2 = 1} \left( \sup_{u_1 \in [-1, 1]} (x_1 - x_2)u_1 \right) = 1. \]

Equation (4.18) becomes
\[ \alpha \geq \sup_{(x_1 - x_2)^2 = 1} \left( \inf_{u_1 \in [-1, 1]} (x_1 - x_2)u_1 \right) = -1. \]

From Theorem 4.6, \( V(x_1, x_2) = \max(|x_1 - x_2|, 1) \) is a bisimulation function between \( T_{\Delta_1} \) and \( T_{\Delta_2} \). Let us remark that this example illustrates an important difference between approximate bisimulation and model reduction techniques. Indeed, our approach allows to abstract (i.e. to ignore) the input of a system which does not make sense in the model reduction framework.

Note that our approach is consistent with our previous results. Indeed, if equation (4.7) holds, then we can choose \( \alpha = 0 \) and have a bisimulation function of the form \( V(x_1, x_2) = \sqrt{x^TMx} \). The advantage of considering truncated quadratic simulation functions over purely quadratic simulation functions is that they are universal for the class of stable constrained linear systems.

**Proposition 4.8.** Let \( \Delta_1 \) and \( \Delta_2 \) be asymptotically stable constrained linear systems, then there exists a bisimulation function of the form (4.11) between \( T_{\Delta_1} \) and \( T_{\Delta_2} \).

**Proof.** First, let us remark that equation (4.16) is equivalent to
\[ (A + \lambda I)^TM + M(A + \lambda I) \leq 0. \]
Then, since all the real parts of the eigenvalues of $A_1$ and $A_2$ are strictly negative, it follows that for $\lambda$ small enough, the real parts of the eigenvalues of $A + \lambda I$ are all strictly negative. Hence, similar to the proof of Proposition 4.3, we can show that there exists a matrix $M$ such that equations (4.15) and (4.16) hold. Moreover,

$$
\sup_{x^TMx=1} \left( \sup_{u_1 \in U_1} \inf_{u_2 \in U_2} x^TM(B_1u_1 + B_2u_2) \right) \leq \sup_{x^TMx=1} \left( \sup_{u_1 \in U_1} \sup_{u_2 \in U_2} x^TM(B_1U_1 + B_2U_2) \right) \\
\quad \leq \sup_{u_1 \in U_1} \sup_{u_2 \in U_2} \left( \sup_{x^TMx=1} x^TM(B_1u_1 + B_2u_2) \right) \\
\quad \leq \sup_{u_1 \in U_1} \sup_{u_2 \in U_2} \sqrt{(B_1u_1 + B_2u_2)^TM(B_1u_1 + B_2u_2)}.
$$

Since, $U_1$ and $U_2$ are compact sets, it is easy to see that there exists $\alpha \geq 0$ such that (4.17) holds. By a symmetric reasoning, we can show that there exists $\alpha \geq 0$ such that (4.18) also holds. \hfill \Box

**Corollary 4.9.** Let $\Delta_1$ and $\Delta_2$ be asymptotically stable constrained linear systems, then $T_{\Delta_1}$ and $T_{\Delta_2}$ are approximately bisimilar.

**Proof.** The proof is straightforward from the fact that the game given by equation (2.1) has obviously a finite value since $I_1$ and $I_2$ are compact sets. \hfill \Box

### 4.3. Handling instability.

If $\Delta_1$ and $\Delta_2$ are not asymptotically stable, the results of the previous section cannot be used directly. Indeed, it is implicitly assumed that there exists a bisimulation function between $T_{\Delta_1}$ and $T_{\Delta_2}$ with finite values on $\mathbb{R}^{n_1} \times \mathbb{R}^{n_2}$. From Theorem 2.5, this implies that for any $(x_1, x_2) \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}$, for any trajectory of $\Delta_1$ starting in $x_1$, there exists a trajectory of $\Delta_2$ starting in $x_2$ and such that the distance between the observations of these trajectories remains bounded (and conversely). When dealing with unstable dynamics, it is not hard to see that this is generally not the case and that bisimulation functions with finite values on $\mathbb{R}^{n_1} \times \mathbb{R}^{n_2}$ cannot exist.

In the following, we search for simulation functions whose values are finite on a subspace of $\mathbb{R}^{n_1} \times \mathbb{R}^{n_2}$. Let $E_{u,i}$ (respectively $E_{s,i}$) be the subspace of $\mathbb{R}^{n_i}$ spanned by the generalized eigenvectors of $A_i$ associated to eigenvalues whose real part is positive (respectively strictly negative). Note that we have $E_{u,i} \oplus E_{s,i} = \mathbb{R}^{n_i}$. Let $P_{u,i}$ and $P_{s,i}$ denote the associated projections. $E_{u,i}$ and $E_{s,i}$ are invariant under $A_i$ and are called the unstable and the stable subspaces of the system $\Delta_i$. Using a change of coordinates, the matrices of system $\Delta_i$ can be transformed into the following form

$$
(4.19) \quad A_i = \begin{bmatrix} A_{u,i} & 0 \\ 0 & A_{s,i} \end{bmatrix}, \quad B_i = \begin{bmatrix} B_{u,i} \\ B_{s,i} \end{bmatrix}, \quad C_i = \begin{bmatrix} C_{u,i} & C_{s,i} \end{bmatrix},
$$

where all the eigenvalues of $A_{u,i}$ have a positive real part and all the eigenvalues of $A_{s,i}$ have a strictly negative real part. Let us define the unstable subsystems of $\Delta_1$ and $\Delta_2$

$$
\Delta_{u,i} : \begin{cases} 
\dot{x}_{u,i}(t) = A_{u,i}x_{u,i}(t) + B_{u,i}u_i(t), \quad x_{u,i}(t) \in E_{u,i}, \quad u_i(t) \in U_i, \quad x_{u,i}(0) \in P_{u,i}I_i \\
y_{u,i}(t) = C_{u,i}x_{u,i}(t), \quad y_{u,i}(t) \in \mathbb{R}^p
\end{cases}
$$

Let $T_{\Delta_{u,1}}$ and $T_{\Delta_{u,2}}$ be the associated metric transition systems. For $j \in \{u, s\}$, we define the matrices

$$
(4.20) \quad A_j = \begin{bmatrix} A_{j,1} & 0 \\ 0 & A_{j,2} \end{bmatrix}, \quad B_{j,1} = \begin{bmatrix} B_{j,1} \\ 0 \end{bmatrix}, \quad B_{j,2} = \begin{bmatrix} 0 \\ B_{j,2} \end{bmatrix}, \quad C_j = \begin{bmatrix} C_{j,1} & -C_{j,2} \end{bmatrix}.
$$
and the projections defined by

\[ P_j x = \begin{bmatrix} P_{j,1} x_1 \\ P_{j,2} x_2 \end{bmatrix}. \]

In the following, we show that if there exists subspace \( \mathcal{R}_u \subseteq E_{u,1} \times E_{u,2} \) which is an exact bisimulation relation between \( T_{\Delta u,1} \) and \( T_{\Delta u,2} \), then we are able to compute a bisimulation function between \( T_{\Delta 1} \) and \( T_{\Delta 2} \).

**Lemma 4.10.** Let \( \mathcal{R}_u \subseteq E_{u,1} \times E_{u,2} \) be a subspace satisfying:

\[
(4.21) \quad \mathcal{R}_u \subseteq \ker(C_u),
\]
\[
(4.22) \quad A_u \mathcal{R}_u \subseteq \mathcal{R}_u,
\]
\[
(4.23) \quad \mathcal{R}_u + \bar{B}_{u,1} U_1 = \mathcal{R}_u - \bar{B}_{u,2} U_2.
\]

Then, \( \mathcal{R}_u \) is an exact bisimulation relation between \( T_{\Delta u,1} \) and \( T_{\Delta u,2} \).

**Proof.** Let \( x_u = (x_{u,1}, x_{u,2}) \in \mathcal{R}_u \), equation (4.21) implies that \( C_{u,1} x_{u,1} = C_{u,2} x_{u,2} \). Let \( x_{u,1} \xrightarrow{t_u,1} x'_{u,1} \), we note \( u_1(.) \) the input that leads \( \Delta_{u,1} \) from \( x_{u,1} \) to \( x'_{u,1} \). From equation (4.23), there exists \( u_2(.) \) an input of \( \Delta_{u,2} \) such that for all \( s \in [0, t] \), \( \bar{B}_{u,1} u_1(s) + \bar{B}_{u,2} u_2(s) \in \mathcal{R}_u \). The input \( u_2(.) \) leads \( \Delta_{u,2} \) from \( x_{u,2} \) to \( x'_{u,2} \). Let us remark that \( x_u = (x'_{u,1}, x'_{u,2}) \) satisfies

\[
x'_u = e^{A_u t} x_u + \int_0^t e^{A_u (t-s)} (\bar{B}_{u,1} u_1(s) + \bar{B}_{u,2} u_2(s)) \, ds.
\]

From equation (4.22), it is then clear that \( (x'_{u,1}, x'_{u,2}) \in \mathcal{R}_u \). Using symmetrical arguments, we can show that for all \( x_{u,2} \xrightarrow{t_{u,2}} x'_{u,2} \), there exist \( x_{u,1} \xrightarrow{t_{u,1}} x'_{u,1} \) such that \( (x'_{u,1}, x'_{u,2}) \in \mathcal{R}_u \). Therefore, \( \mathcal{R}_u \) is an exact bisimulation relation between \( T_{\Delta u,1} \) and \( T_{\Delta u,2} \). \( \square \)

**Remark 4.11.** The characterization of an exact bisimulation relation given by Lemma 4.10 slightly differs from those that can be found in the literature [Pap03, vdS04]. This is due to the fact that the systems considered in these papers do not have constraints on the inputs.

**Proposition 4.12.** Let \( \mathcal{R}_u \subseteq E_{u,1} \times E_{u,2} \) be a subspace satisfying equations (4.21), (4.22) and (4.23). Let \( M_s \) be a positive semi-definite symmetric matrix and \( \alpha_s \) a positive number such that for all for all \( x \in E_{u,1} \times E_{u,2} \),

\[
(4.24) \quad x^T_s M_s x_s \geq x^T_s C_s^T C_s x_s
\]

and for all \( x \in E_{u,1} \times E_{u,2} \), such that \( x^T_s M_s x_s \geq \alpha_s^2 
\]

\[
(4.25) \quad x^T_s M_s A_s x_s + x^T_s A^T s M_s x_s + 2 \sup_{u_1 \in U_1} \left( \inf_{u_2 \in U_2, \bar{B}_{u,1} u_1 + \bar{B}_{u,2} u_2 \in \mathcal{R}_u} x^T_s M_s (\bar{B}_{s,1} u_1 + \bar{B}_{s,2} u_2) \right) \leq 0,
\]

and

\[
(4.26) \quad x^T_s M_s A_s x_s + x^T_s A^T s M_s x_s + 2 \sup_{u_2 \in U_2} \left( \inf_{u_1 \in U_1, \bar{B}_{u,1} u_1 + \bar{B}_{u,2} u_2 \in \mathcal{R}_u} x^T_s M_s (\bar{B}_{s,1} u_1 + \bar{B}_{s,2} u_2) \right) \leq 0.
\]

Then, the function \( V : \mathbb{R}^{n_1} \times \mathbb{R}^{n_2} \to \mathbb{R}^+ \cup \{+\infty\} \) given by

\[
(4.27) \quad V(x) = \begin{cases} +\infty, & \text{if } P_{u} x \notin \mathcal{R}_u \\
\max(\sqrt{x^T P_{u}^T M_s P_{u} x}, \alpha_s), & \text{if } P_{u} x \in \mathcal{R}_u \end{cases}
\]

is a bisimulation function between \( T_{\Delta 1} \) and \( T_{\Delta 2} \).
Proof. Let \((x_1, x_2) \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}\), if \(P_\alpha x \notin R_u\) it is clear that \(V(x) \geq \|Cx\|\). If \(P_\alpha x \in R_u\), from equation (4.21) we have that \(C_s P_\alpha x = 0\). Then, \(\|Cx\| = \|C_s P_\alpha x + C_s P_\xi x\| = \|C_s P_\xi x\|\). From equation (4.24), we have that \(\|Cx\| \leq \sqrt{x^T P_s^T M_s P_s x} \leq V(x)\). Let \(x_1, x_2 \in R_u\), then for any \(x_2 \xrightarrow{t} x_2'\), \(V(x_1', x_2') \leq +\infty = V(x_1, x_2)\). If \(P_\alpha x \in R_u\), then let \(f(x) = x^T P_s^T M_s P_\xi x\). From equation (4.25) and Proposition 3.1 (with \(H = \{(u_1, u_2)| B_{u_1, u_1} + B_{u_2, u_2} \in R_u\}, \eta = \alpha_s^2\)) we have that there exists \(x_2 \xrightarrow{t} x_2'\) such that \(f(x_1', x_2') \leq \max(f(x_1, x_2), \alpha_s^2)\). Moreover, there exist inputs \(u_i(.)\) \((i = 1, 2)\) leading \(\Delta_i\) from \(x_1\) to \(x_1'\) at time \(t\) and such that for all \(s \in [0, t]\), \(\mathbb{B}_{u_1, u_1}(s) + \mathbb{B}_{u_2, u_2}(s) \in R_u\). Now let us remark that

\[
P_\alpha x' = e^{A_\alpha t} P_\alpha x + \int_0^t e^{A_\alpha (t-s)} (\mathbb{B}_{u_1, u_1}(s) + \mathbb{B}_{u_2, u_2}(s)) \, ds.
\]

From equation (4.22), it follows that \(P_\alpha x' \in R_u\). Hence \(V(x_1', x_2') = \max(\sqrt{f(x_1', x_2')}, \alpha_s) \leq \max(f(x_1, x_2), \alpha_s) = V(x_1, x_2)\). By symmetry, we also have that for all \(x_2 \xrightarrow{t} x_2'\), there exists \(x_1 \xrightarrow{t} x_1'\) such that \(V(x_1', x_2') \leq V(x_1, x_2)\). Therefore, \(V\) is a bisimulation function between \(T_{\Delta_1}\) and \(T_{\Delta_2}\).

The following Theorem gives another characterization of such bisimulation functions. The proof is similar to the one of Theorem 4.6 and is therefore not stated here.

**Theorem 4.13.** Let \(R_u \subseteq E_{u_1} \times E_{u_2}\) be a subspace satisfying equations (4.21), (4.22) and (4.23). If there exists \(\lambda_s > 0\), such that

\[
M_s \geq C_s^T C_s,
\]

\[
A_s^T M_s + M_s A_s + 2 \lambda_s M_s \leq 0,
\]

\[
\alpha_s \geq \frac{1}{\lambda_s} \sup_{x_1^T M_s x_1 = 1} \left( \left( \sup_{u_2 \in U_2} \left( \inf_{u_1 \in U_1, B_{u_1, u_1} + B_{u_2, u_2} \in S_u} \left( x_1^T M_s (B_{s, 1, u_1} + B_{s, 2, u_2}) \right) \right) \right) \right).
\]

\[
\alpha_s \geq \frac{1}{\lambda_s} \sup_{x_1^T M_s x_1 = 1} \left( \left( \sup_{u_2 \in U_2} \left( \inf_{u_1 \in U_1, B_{u_1, u_1} + B_{u_2, u_2} \in S_u} \left( x_1^T M_s (B_{s, 1, u_1} + B_{s, 2, u_2}) \right) \right) \right) \right).
\]

Then, the function \(V(x_1, x_2)\) given by equation (4.27) is a bisimulation function between \(T_{\Delta_1}\) and \(T_{\Delta_2}\).

We also have, similar to Proposition 4.8:

**Proposition 4.14.** If there exists a subspace \(R_u\) satisfying equations (4.21), (4.22) and (4.23), then there exists a bisimulation function of the form (4.27) between \(T_{\Delta_1}\) and \(T_{\Delta_2}\).

Then, it follows that two systems with exactly bisimilar unstable subsystems are approximately bisimilar.

**Corollary 4.15.** If there exists a subspace \(R_u\) satisfying equations (4.21), (4.22) and (4.23), and such that for all \(x_{u_1} \in P_{u_1 I_1}\) there exists \(x_{u_2} \in P_{u_2 I_2}\) satisfying \((x_{u_1}, x_{u_2}) \in R_u\) and conversely (i.e. \(T_{\Delta_{u_1}}\) and \(T_{\Delta_{u_2}}\) are exactly bisimilar), then \(T_{\Delta_1}\) and \(T_{\Delta_2}\) are approximately bisimilar.
Proof. Let $V(x_1, x_2)$ be a bisimulation function of the form (4.27) between $T_{\Delta_1}$ and $T_{\Delta_2}$. For all $x_1 \in I_1$, there exists $x_2 \in I_2$ such that $P_u x \in R_u$ then,

$$\sup_{x_1 \in I_1} \inf_{x_2 \in I_2} V(x_1, x_2) = \sup_{x_1 \in I_1} \left( \inf_{x_2 \in I_2, P_u x \in R_u} \max(\sqrt{x^T P_s^T M_s P_s x}, \alpha_s) \right).$$

Since $I_1$ and $I_2$ are compact sets, this game has a finite value. Symmetrically, we also have that the value of

$$\sup_{x_2 \in I_2} \inf_{x_1 \in I_1} V(x_1, x_2) = \sup_{x_2 \in I_2} \left( \inf_{x_1 \in I_1, P_u x \in R_u} \max(\sqrt{x^T P_s^T M_s P_s x}, \alpha_s) \right)$$

is finite and thus from Theorem 2.9, $T_{\Delta_1}$ and $T_{\Delta_2}$ are approximately bisimilar. \hfill \Box

5. APPROXIMATION OF LINEAR SYSTEMS USING APPROXIMATE BISIMULATION

In this section, we use the previous results to compute the precision of the approximate bisimulation between a linear system with constrained inputs $\Delta_1$ of the form (3.1) and a projection $\Delta_2$. Let us assume, without loss of generality that the system $\Delta_1$ has been decomposed into a stable and unstable subsystems and that the matrices $A_1, B_1, C_1$ are of the form given by equation (4.19). Given a surjective map $x_2 = H x_1$, we define the projection of $\Delta_1$ as the linear system with constrained inputs $\Delta_2$ given by:

\begin{equation}
A_2 = HA_1 H^+, B_2 = HB_1, C_2 = C_1 H^+, U_2 = U_1 \text{ and } I_2 = H I_1
\end{equation}

where $H^+$ denotes the Moore-Penrose pseudoinverse of $H$. For simplicity, we will assume that the map $H$ is of the form:

$$H = \begin{bmatrix} H_u & 0 \\ 0 & H_s \end{bmatrix}.$$

Then,

$$A_2 = \begin{bmatrix} H_u A_{u,1} H^+_u & 0 \\ 0 & H_s A_{s,1} H^+_s \end{bmatrix}, B_2 = \begin{bmatrix} H_u B_{u,1} \\ H_s B_{s,1} \end{bmatrix} \text{ and } C_2 = [C_{u,1} H^+_u C_{s,1} H^+_s].$$

Hence, the matrices $A_2, B_2, C_2$ are also of the form given by equation (4.19).

**Lemma 5.1.** The subspace $R_u \subseteq E_{u,1} \times E_{u,2}$ given by

$$R_u = \{(x_{u,1}, x_{u,2}) \mid x_{u,2} = H_u x_{u,1}\}$$

satisfies equations (4.21), (4.22) and (4.23) if and only if

\begin{equation}
C_{u,1} = C_{u,1} H^+_u H_u,
\end{equation}

\begin{equation}
H_u A_{u,1} = H_u A_{u,1} H^+_u H_u.
\end{equation}

In that case, $T_{\Delta_{u,1}}$ and $T_{\Delta_{u,2}}$ are exactly bisimilar.

**Proof.** First, let us remark that

$$C_{u,1} = C_{u,1} H^+_u H_u \iff C_{u,1} - C_{u,2} H_u = 0 \iff R_u \subseteq \ker(C_u).$$

Secondly,

$$H_u A_{u,1} = H_u A_{u,1} H^+_u H_u \iff H_u A_{u,1} = A_{u,2} H_u \iff A_u R_u \subseteq R_u.$$

Finally, for all $u \in U_1$, $H_u B_{u,1} u = B_{u,2} u$. Since $U_1 = U_2$, equation (4.23) holds. From Lemma 4.10, $R_u$ is an exact bisimulation relation between $T_{\Delta_{u,1}}$ and $T_{\Delta_{u,2}}$. From the specific form of $H$, we have for all $x_1 \in \mathbb{R}^{n_1}$, $H_s P_{u,1} x_1 = H_{u,2} H x_1$. Then, for all $x_{u,1} \in P_{u,1} I_1$, $x_{u,1} = P_{u,1} x_1$ with $x_1 \in I_1$. Let $x_{u,2} = H_u x_{u,1} = H_u P_{u,1} x_1 = P_{u,2} H x_1$, hence $x_{u,2} \in P_{u,2} I_2$ and $(x_{u,1}, x_{u,2}) \in R_u$. 

Let us remark that we assumed that \( \delta \) is such that the eigenvalues of the matrix \( H_sA_sH_s^T \) have all a strictly negative real part. Then, from Proposition 4.14, we know that there exists a bisimulation function between \( T_{\Delta_1} \) and \( T_{\Delta_2} \) of the form (4.27). Let \( A_s, B_{s,1}, B_{s,2} \) and \( C_s \) be defined as in equation (4.20). There exist a matrix \( M_s \) and a real number \( \lambda_s > 0 \) satisfying equations (4.28) and (4.29). Let us define the matrix

\[
Q_s = \begin{bmatrix} I & H_s^T \\ H_s & M_s \end{bmatrix}.
\]

**Theorem 5.2.** Let \( \alpha_s \) be defined by

\[
(5.4) \quad \alpha_s = \frac{1}{\lambda_s} \sup_{u_1 \in U_1} \sqrt{u_1^T B_{s,1}^T Q_s B_{s,1} u_1}.
\]

Then, the function \( V \) defined by

\[
V(x) = \begin{cases} 
+\infty, & \text{if } P_x \notin \ker((H_u - I)) \\
\max \left( \sqrt{x^T P_x M_s P_x}, \alpha_s \right), & \text{if } P_x \in \ker((H_u - I))
\end{cases}
\]

is a bisimulation function between \( T_{\Delta_1} \) and \( T_{\Delta_2} \).

**Proof.** We assumed that \( H_u \) is such that \( \ker((H_u - I)) \) satisfies equations (4.21), (4.22), (4.23). Furthermore, \( M_s \) and \( \lambda_s \) satisfy equations (4.28) and (4.29). Now, let us remark that

\[
\alpha_s = \frac{1}{\lambda_s} \sup_{u_1 \in U_1} \sqrt{u_1^T (B_{s,1} + B_{s,2})^T M_s (B_{s,1} + B_{s,2}) u_1} = \frac{1}{\lambda_s} \sup_{x^T M_s x \neq 0} \left( \sup_{u_1 \in U_1} \frac{x^T M_s (B_{s,1} + B_{s,2}) u_1}{\sqrt{u_1^T (B_{s,1} + B_{s,2})^T M_s (B_{s,1} + B_{s,2}) u_1}} \right) \geq \frac{1}{\lambda_s} \sup_{x^T M_s x \neq 0} \left( \sup_{u_1 \in U_1} \left( \sup_{u_2 \in U_2} \frac{\inf_{\ker((H_u - I))} x^T M_s (B_{s,1} u_1 + B_{s,2} u_2)}{x^T M_s (B_{s,1} u_1 + B_{s,2} u_2)} \right) \right).
\]

Then, equation (4.30) holds. Since \( U_1 = U_2 \), equation (4.31) holds as well. Then, from Theorem 4.13, \( V \) is a bisimulation function between \( T_{\Delta_1} \) and \( T_{\Delta_2} \). \( \square \)

From Theorem 2.9, the precision of the approximate bisimulation between \( T_{\Delta_1} \) and \( T_{\Delta_2} \) can be evaluated by solving the game (2.1).

**Theorem 5.3.** Let \( \alpha_s \) be defined as in equation (5.4), let \( \beta_s \) be defined as

\[
(5.5) \quad \beta_s = \sup_{x_1 \in I_1} \sqrt{x_1^T P_{s,1}^T Q_s P_{s,1} x_1}.
\]

Let \( \delta = \max(\alpha_s, \beta_s) \). Then, \( T_{\Delta_1} \) and \( T_{\Delta_2} \) are approximately bisimilar with the precision \( \delta \).

**Proof.** Let us remark that

\[
\beta_s = \sup_{x_1 \in I_1} \sqrt{\left[ x_1^T P_{s,1}^T \quad x_1^T P_{s,1}^T H_s^T \right] M_s \left[ \begin{array}{c} P_{s,1} x_1 \\ H_s P_{s,1} x_1 \end{array} \right]}.
\]
From the block diagonal structure of $H$ we have that $P_s^2H = H_s P_{s,1}$. Hence,

$$\beta_s = \sup_{x_1 \in I_1} \left( x_1^T x_1^T H_s^T P_s^T M_s P_s \left[ \begin{array}{c} x_1 \\ H x_1 \end{array} \right] \right)$$

$$= \sup_{x_1 \in I_1} \left( \inf_{x_2 \in I_2, x_2 = H_1} \sqrt{x_2^T P_s^T M_s P_s x} \right)$$

$$\geq \sup_{x_1 \in I_1} \left( \inf_{x_2 \in I_2, P_s x \in \ker([H_s - I])} \sqrt{x_2^T P_s^T M_s P_s x} \right).$$

Similarly, we also have,

$$\beta_s = \sup_{x_2 \in H_1} \left( \inf_{x_1 \in I_1, x_2 = H_1} \sqrt{x_2^T P_s^T M_s P_s x} \right)$$

$$\geq \sup_{x_2 \in H_1} \left( \inf_{x_1 \in I_1, P_s x \in \ker([H_s - I])} \sqrt{x_2^T P_s^T M_s P_s x} \right).$$

Hence, the value of the game (2.1) is bounded by $\max(\alpha_s, \beta_s)$ which implies, from Theorem 2.9, that $\Delta_1$ and $\Delta_2$ are approximately bisimilar with the precision $\delta$. $\square$

We presented a method to evaluate the precision of the approximate bisimulation between a constrained linear system and its projection. From the computational point of view, it requires to solve a set of linear matrix inequalities which can be done using semi-definite programming [Stu99]. Then, if we assume that $I_1$ and $U_1$ are polytopes, the precision of the approximate bisimulation between a constrained linear system and its projection can be computed by solving two linear quadratic programs given by equations (5.4) and (5.5). The method is summarized in the following algorithm:

**Algorithm 5.4.** Let $\Delta_1$ be a constrained linear system and $\Delta_2$ its projection given by equation (5.1).

1. Check that $C_{u,1} = C_{u,1} H_u^+ H_u$ and $H_u A_{u,1} = H_u A_{u,1} H_u^+ H_u$.
2. Choose $\lambda_s > 0$ such that the eigenvalues of $A_s + \lambda_s I$ have a strictly negative real part. Then, solve the linear matrix inequalities:

$$M_s \geq C_s^T C_s,$$

$$A_s^T M_s + M_s A_s + 2\lambda_s M_s \leq 0,$$

and set

$$Q_s = \left[ \begin{array}{cc} I & H_s^T \\ H_s & 0 \end{array} \right] M_s \left[ \begin{array}{c} I \\ H_s \end{array} \right].$$

3. Solve the linear quadratic program

$$\gamma_1 = \max_{u_1 \in U_1} u_1^T B_{s,1}^T Q_s B_{s,1} u_1$$

and set $\alpha_s = \sqrt{\gamma_1} / \lambda_s$.
4. Solve the linear quadratic program

$$\gamma_2 = \max_{x_1 \in I_1} x_1^T P_{s,1}^T Q_s P_{s,1} x_1$$

and set $\beta_s = \sqrt{\gamma_2}$.
5. Let $\delta = \max(\alpha_s, \beta_s)$.

Then, $\Delta_1$ and $\Delta_2$ are approximately bisimilar with the precision $\delta$. 

An important parameter in this algorithm is the strictly positive scalar $\lambda_s$. On one hand, $\lambda_s$ must be chosen small enough so that the eigenvalues of $A_s + \lambda_s I$ have a strictly negative real part. On the other hand, it appears experimentally that the larger $\lambda_s$, the better the evaluation of the precision of the approximate bisimulation between $T_{\Delta_1}$ and $T_{\Delta_2}$.

The resolution of the linear matrix inequalities can be done using semi-definite programming [Stu99]. It should be noted that the smaller the matrix $Q_s$ the smaller the precision $\delta$. Hence, to get a tight evaluation of the precision of the approximate bisimulation between $T_{\Delta_1}$ and $T_{\Delta_2}$, it is useful to add to the semi-definite program a linear objective function which can be, for instance, the trace of $Q_s$. For very large systems, the resolution of the semi-definite program can be costly. In such cases, the linear matrix inequalities can be solved by replacing them by a Lyapunov equation as in the proof of Proposition 4.3. The evaluation of the precision $\delta$ is not as tight, but the computations are much faster.

The remaining question is how do we choose the surjective map $H$ so that the precision of the approximate bisimulation between $T_{\Delta_1}$ and its projection $T_{\Delta_2}$ of desired dimension is as small as possible. First, it is to be noted that the choice of $H_u$ is quite restricted. Any bijective map is obviously an admissible choice for $H_u$. Using exact bisimulation reduction techniques [Pap03, TP03, vdS04], admissible surjective but non-bijective maps $H_u$ can be chosen.

The choice of $H_s$ is much less constrained and thus much more difficult. For instance, it can be chosen according to traditional model reduction techniques such as balanced truncation [ASG00]. It appears that in the context of approximate bisimulation these techniques have quite poor results. This is due to the fact that traditional model reduction techniques aim to approximate the input-output mapping associated to a linear system: the transient behavior is completely ignored (the initial state is assumed to be 0). We have seen that in the context of approximate bisimulation, the transient phase is as important as the asymptotic phase. Therefore, it is not surprising that model reduction techniques are not of great help for the choice of the map $H_s$. Then, $H_s$ can be chosen using the following heuristic. Define $H_s$ as the projection on the subspace of $E_{s,1}$ of desired dimension, invariant under $A_{s,1}$ and which is the most likely to minimize the optimal value of the optimization problems (5.4) and (5.5). Experimentally, it appears that, most of the time, this heuristic gives better result than model reduction techniques. However, it is clearly not optimal. Further research is definitely needed to design better methods to find a good surjective map $H_s$.

Our method has been implemented in a MATLAB toolbox available for download: MATISSE (Metricals for Approximate Transition Systems Simulation and Equivalence [GJP05]). It uses several toolboxes such as the Multi-Parametric Toolbox [KGB04] for polytopes manipulation, the interface YALMIP [Löf04] to translate linear matrix inequalities into semi-definite programs which are solved by the toolbox SEDUMI [Stu99]. MATISSE allows to reduce a constrained linear system $\Delta_1$ to a system $\Delta_2$ of given dimension, and to compute the precision of the approximate bisimulation between $T_{\Delta_1}$ and $T_{\Delta_2}$.

6. Examples

In this section, we show two examples of application of the toolbox MATISSE\(^1\). The first one deals with a middle-scale system (dimension ten). It is shown how MATISSE can be used in the context of safety verification to reduce the complexity of the problem. The second one deals with a large-scale system (about a hundred continuous variables).

\(^1\)This examples are available as demo files in MATISSE.
6.1. Middle-scale system. Let us consider $\Delta_1$, the ten dimensional system with a one dimensional input given by the following matrices:

$$
A_1 = \begin{bmatrix}
-0.1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
-1 & -0.1 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 \\
0 & 0 & -0.3 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & -0.1 & -8 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & -0.1 & -1 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -0.1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -0.1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{bmatrix},
B_1 = \begin{bmatrix}
0 \\
0 \\
0 \\
0 \\
0 \\
0 \\
0 \\
0 \\
0 \\
0 \end{bmatrix},
C_1^T = \begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{bmatrix}.
$$

The input is constrained in the interval $[-0.05, 0.05]$ and the initial value is constrained in the rectangle

$$
I_1 = [9, 10] \times [0, 1] \times [-0.1, 0.1]^2 \times [-2, 1] \times [-0.1, 0.1]^5.
$$

$\Delta_1$ is asymptotically stable, thus it is already of the form (4.19). We compute approximations $\Delta_2$ of dimension five and $\Delta_3$ of dimension seven using the heuristic described in the previous section and implemented in ASILIS. Then, using Algorithm 5.4, we evaluate the precision of the approximate bisimulation between $T_{\Delta_1}$ and its approximations. If the linear matrix inequalities are solved using semi-definite programming, the evaluation of the precision of the approximate bisimulation between $T_{\Delta_1}$ and $T_{\Delta_2}$ is 2.016. The computation requires 5.48 seconds. If the linear matrix inequalities are solved using Lyapunov equations, the evaluation of the precision of the approximate bisimulation between $T_{\Delta_1}$ and $T_{\Delta_2}$ is 4.636 and the computation requires 0.12 seconds. Similarly, the evaluation of the precision of approximate bisimulation between $T_{\Delta_1}$ and $T_{\Delta_3}$ using semi-definite programming is 0.359 (computation time: 6.11 seconds). Using Lyapunov equations, it is 4.072 (computation time: 0.12 seconds). Thus, we can see that the method using semi-definite programming gives much better evaluations of the precision of the approximate bisimulation between $T_{\Delta_1}$ and its approximations than the method using Lyapunov equations. However, the latter requires much less computation and can therefore handle larger systems.

Reachability routines based on zonotope computation [Gir05] have been implemented in MATISSE. On figure 1, we represented the reachable set of the original ten dimensional system (left) and of its five dimensional and seven dimensional approximations (center and right). We also represented the unsafe set $\Pi_U$. For the approximations, this set is bloated by the precision of the approximate bisimulation between $T_{\Delta_1}$ and its approximations (evaluated using semi-definite programming). It follows that if an approximation is safe then the original system is safe. We can see that the approximation of dimension 7 allows to conclude that the original system is safe, whereas the approximation of dimension 5 does not.

The example also illustrates the important point that robustness simplifies verification. Indeed, if the distance between the reachable set of the original system and the set of unsafe states would have been larger, then the approximation of the original system by its five dimensional approximation $T_{\Delta_5}$ might have been sufficient to check the safety. Further, we might have been able to conclude that the system is safe using the precision of the approximate bisimulation between $T_{\Delta_1}$ and $T_{\Delta_2}$ evaluated using Lyapunov equations. Generally, the more robustly safe a system is, the larger the distance from the unsafe safe, resulting in larger model compression and easier safety verification.
6.2. Large-scale system. Let us now consider the following problem [CD02]. We consider the heat diffusion equation on a rod:

\[
\begin{align*}
\frac{\partial}{\partial t} T(x, t) &= \alpha \frac{\partial^2}{\partial x^2} T(x, t) + u(x, t), \quad x \in (0, 1), \ t > 0, \\
T(0, t) &= 0 = T(1, t), \quad t > 0, \\
T(x, 0) &= 0, \quad x \in (0, 1)
\end{align*}
\]

where \( T(x, t) \) represents the temperature field on the rod. We assume that the heat source is of the form \( u(x, t) = \frac{\delta_{1/3}(x)}{u(t)} \) where \( u(t) \in [1, 1.1] \). The system is observed through the temperature at the point \( 2/3 \): \( y(t) = T(2/3, t) \). The partial differential equation is discretized in space (101 nodes). This 101 dimensional linear system with a one-dimensional input is our original system \( \Delta_1 \).

We compute approximations \( \Delta_2 \) of dimension ten and \( \Delta_3 \) of dimension twenty. The evaluation of the precision of the approximate bisimulation between \( T_{\Delta_1} \) and its approximations is done using Lyapunov equations. It requires respectively 1.81 and 1.92 seconds. \( T_{\Delta_1} \) and \( T_{\Delta_2} \) are approximately bisimilar with the precision 1.27 whereas \( T_{\Delta_1} \) and \( T_{\Delta_3} \) are approximately bisimilar with the precision 0.32. On figure 2, we represented the evolution of the reachable sets of \( T_{\Delta_1} \) and \( T_{\Delta_2} \) against time.

It is clear that the distance between the reachable sets is actually much smaller than the precision of the approximate simulation between \( T_{\Delta_1} \) and \( T_{\Delta_2} \) given by Algorithm 5.4. This is due to the use of Lyapunov equations to solve the linear matrix inequalities which gives a large evaluation of the precision. However, in the context of safety verification, if \( T_{\Delta_1} \) is robustly safe then this evaluation of the precision might well be sufficient to conclude that \( T_{\Delta_1} \) is safe by performing the reachability analysis on \( T_{\Delta_2} \).

7. Conclusion

In this paper, we applied the framework of system approximation based on approximate versions of bisimulation relations to a class of constrained linear systems. We presented a class of functions which provide universal bisimulation functions for such systems. An important consequence, is that any two systems with exactly bisimilar unstable subsystems are approximately bisimilar. We gave effective characterizations for this class of bisimulation functions allowing us to develop an efficient algorithm to compute the precision of the approximate bisimulation between a system and its projection. This
algorithm only requires the resolution of a set of linear matrix inequalities and of two linear quadratic programs and is therefore computationally effective.

This algorithm has been implemented within a MATLAB toolbox, MATISSE [GJP05]. MATISSE allows to reduce a constrained linear system to a system of given dimension and to compute the precision of the approximate bisimulation between the original system and its approximation. Two examples a application of MATISSE were showed. Particularly, we saw that, coupled to reachable set computation methods, it can be used to solve more efficiently the safety verification problem of linear systems.

Future research includes extending the results for linear systems to stochastic linear systems. We also aim to develop such computational techniques for nonlinear and hybrid systems.

References

Proof of Proposition 3.1. The proof of Proposition 3.1 requires several preliminary results.

Lemma 7.1. Let \((x_1, x_2) \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}\), let \(t > 0\), then for all \(\varepsilon > 0\), there exists \(h > 0\) such that for all inputs \(u_1(.)\) and \(u_2(.)\) of \(\Delta_1\) and \(\Delta_2\), and associated trajectories 

\[
\forall s \in [0, t], \quad z_i(s) = e^{A_i s}x_i + \int_0^s e^{A_i(s-\tau)}B_i u_i(\tau) d\tau, \quad i = 1, 2
\]

we have for all \(u_1 \in U_1, u_2 \in U_2, s, s' \in [0, t]\),

\[s \leq s' \leq s + h \implies |\nabla f(z(s))(Az(s) + B_1 u_1 + B_2 u_2) - \nabla f(z(s'))(Az(s') + B_1 u_1 + B_2 u_2)| \leq \varepsilon / t\]

where \(z(s) = (z_1(s), z_2(s))\).

Proof. First let us remark that for all inputs \(u_1(.)\) and \(u_2(.)\) of \(\Delta_1\) and \(\Delta_2\), the associated trajectories are bounded on \([0, t]\):

\[
\forall s \in [0, t], \quad \|z_i(s)\| \leq e^{\|A_i\|t} \|x_i\| + \int_0^t e^{\|A_i\|((t-\tau)}\|B_i\| d\tau \sup_{u_i \in U_i} \|u_i\| = m_i, \quad i = 1, 2.
\]

Note that \(C_1 = \{z_1 \in \mathbb{R}^{n_1} | \|z_1\| \leq m_1\}\) and \(C_2 = \{z_2 \in \mathbb{R}^{n_2} | \|z_2\| \leq m_2\}\) are compact sets. Then, since \(\nabla f(z)(Az + B_1 u_1 + B_2 u_2)\) is continuous on \(\mathbb{R}^{n_1} \times \mathbb{R}^{n_2} \times \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}\) it is absolutely continuous on \(C_1 \times C_2 \times U_1 \times U_2\). Particularly, for all \(\varepsilon > 0\), there exists \(\xi > 0\) such that for all \(u_1 \in U_1, u_2 \in U_2, z_1, z_1' \in C_1, z_2, z_2' \in C_2\):

\[
\|z_1 - z_1'\| \leq \xi \text{ and } \|z_2 - z_2'\| \leq \xi \implies |\nabla f(z)(Az + B_1 u_1 + B_2 u_2) - \nabla f(z')(Az' + B_1 u_1 + B_2 u_2)| \leq \varepsilon / t
\]

where \(z = (z_1, z_2), z' = (z_1', z_2')\).

Now, let us remark that for all inputs \(u_1(.)\) and \(u_2(.)\) of \(\Delta_1\) and \(\Delta_2\), the associated trajectories satisfy for all \(s, s' \in [0, t]\), with \(s \leq s'\),

\[
\|z_i(s') - z_i(s)\| \leq e^{\|A_i\|s} (e^{\|A_i\|(s'-s)} - 1) \|x_i\| + \int_s^{s'} e^{\|A_i\|(s'-\tau)} \|B_i\| d\tau \sup_{u_i \in U_i} \|u_i\|
\]

\[
\leq (e^{\|A_i\|(s'-s)} - 1) \left( e^{\|A_i\|t} \|x_i\| + \sup_{u_i \in U_i} \|u_i\| \right), \quad i = 1, 2.
\]

Therefore, there exists \(h > 0\) such that for all inputs \(u_1(.)\) and \(u_2(.)\) of \(\Delta_1\) and \(\Delta_2\), the associated trajectories \(z_1(.)\) and \(z_2(.)\) satisfy for all \(s, s' \in [0, t]\)

\[
s \leq s' \leq s + h \implies \|z_1(s) - z_1(s')\| \leq \xi \text{ and } \|z_2(s) - z_2(s')\| \leq \xi.
\]

Moreover from equation (7.1), for all \(s, s' \in [0, t]\), we have \(z_1(s), z_1(s') \in C_1, z_2(s), z_2(s') \in C_2\). Then, equations (7.2) and (7.4) allow to conclude. □
Lemma 7.2. Let $f$ be a function and $H$ a subspace satisfying assumptions of Proposition 3.1. Then, for all $(x_1, x_2)$ satisfying $f(x_1, x_2) \geq \eta$, for all $x_1 \overset{t_{i-1}}{\to} x'_1$, for all $\varepsilon > 0$, there exists $x_2 \overset{t_i}{\to} x'_2$ such that

(7.5) \quad f(x'_1, x'_2) \leq f(x_1, x_2) + \varepsilon.

Moreover, there exist inputs $u_i(.)$ ($i = 1, 2$) leading $\Delta_i$ from $x_i$ to $x'_i$ at time $t$ and such that for all $s \in [0, t]$, $(u_1(s), u_2(s)) \in H$.

Proof. Let $(x_1, x_2) \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}$ such that $f(x_1, x_2) \geq \eta$, let $x_1 \overset{t_{i-1}}{\to} x'_1$, let $u_1(.)$ be an input which leads $\Delta_1$ from $x_1$ to $x'_1$ and $z_1(.)$ the associated trajectory of $\Delta_1$. Let $\varepsilon > 0$, let $h > 0$ be given as in Lemma 7.1 (we assume without loss of generality that $t/h = N \in \mathbb{N}$). From equation (3.2), there exists an input $u_2(.)$ for $\Delta_2$ such that

\[ \forall s \in [0, h], (u_1(s), u_2(s)) \in H \text{ and } \nabla f(x)(Ax + \overline{B}_1u_1(s) + \overline{B}_2u_2(s)) \leq 0. \]

Let $z_2(.)$ be the associated trajectory of $\Delta_2$, then

\[ f(z(h)) - f(x) = \int_0^h \nabla f(z(s))(Az(s) + \overline{B}_1u_1(s) + \overline{B}_2u_2(s)) ds. \]

Then, from Lemma 7.1,

\[ f(z(h)) - f(x) \leq \int_0^h \nabla f(z(0))(Az(0) + \overline{B}_1u_1(s) + \overline{B}_2u_2(s)) + \varepsilon/t ds \leq \frac{h\varepsilon}{t}. \]

Now let us assume that for some $i \in \{1, \ldots, N-1\}$ there exists an input $u_2(.)$ for $\Delta_2$ such that

(7.6) \quad \forall s \in [0, ih], (u_1(s), u_2(s)) \in H \text{ and } f(z(ih)) - f(x) \leq \frac{ih\varepsilon}{t}.

We showed that this is true for $i = 1$.

If $f(z(ih)) \geq \eta$, then, according to equation (3.2), we can choose $u_2(.)$ on $[ih, (i+1)h]$ such that

\[ \forall s \in [ih, (i+1)h], (u_1(s), u_2(s)) \in H \text{ and } \nabla f(z(ih))(Az(ih) + \overline{B}_1u_1(s) + \overline{B}_2u_2(s)) \leq 0. \]

Then from Lemma 7.1,

\[ f(z((i+1)h)) - f(z(ih)) \leq \int_{ih}^{(i+1)h} \nabla f(z(ih))(Az(ih) + \overline{B}_1u_1(s) + \overline{B}_2u_2(s)) + \varepsilon/t ds \leq \frac{(i+1)h\varepsilon}{t}. \]

Hence,

\[ \forall s \in [0, (i+1)h], (u_1(s), u_2(s)) \in H \text{ and } f(z((i+1)h)) - f(x) \leq \frac{(i+1)h\varepsilon}{t}. \]

Let us assume that $f(z(ih)) < \eta$. Let $v_2(.)$ be an input of $\Delta_2$ such that

\[ \forall s \in [ih, (i+1)h], (u_1(s), v_2(s)) \in H. \]

Let $w_2(.)$ be the solution of the differential equation

\[ \forall s \in [ih, (i+1)h], \ w_2(s) = A_2w_2(s) + B_2v_2(s), w_2(ih) = z_2(ih). \]

If $f(z_1((i+1)h), w_2((i+1)h)) \leq \eta$, then we choose for all $s \in [ih, (i+1)h], w_2(s) = v_2(s)$ and therefore

\[ f(z((i+1)h)) - f(x) \leq \eta - f(x) \leq 0 \leq \frac{(i+1)h\varepsilon}{t}. \]
If \( f(z_1((i+1)h), w_2((i+1)h)) > \eta \), there exists \( s^* \in (ih, (i+1)h) \), such that \( f(z_1(s^*), w_2(s^*)) = \eta \). Let \( z^* = (z_1(s^*), w_2(s^*)) \). Then, according to equation (3.2), we can choose \( u_2(.) \) such that

\[
\forall s \in [ih, s^*) \quad u_2(s) = v_2(s),
\]

\[
\forall s \in [s^*, (i+1)h], \quad (u_1(s), u_2(s)) \in \mathcal{H} \text{ and } \nabla f(z^*) \left( A z^* + \overline{B}_1 u_1(s) + \overline{B}_2 u_2(s) \right) \leq 0.
\]

Then, from Lemma 7.1,

\[
f(z((i+1)h)) - f(z(s^*)) \leq \int_{s^*}^{(i+1)h} \nabla f(z^*) \left( A z^* + \overline{B}_1 u_1(s) + \overline{B}_2 u_2(s) \right) + \varepsilon/t \ ds \leq \frac{h\varepsilon}{t}.
\]

Hence, for all \( s \in [0, (i+1)h], \ (u_1(s), u_2(s)) \in \mathcal{H} \) and

\[
f(z((i+1)h)) - f(x) \leq f(z((i+1)h)) - \eta \leq \frac{h\varepsilon}{t} \leq \frac{(i+1)h\varepsilon}{t}.
\]

Then equation (7.6) holds for all \( i \in \{1, \ldots, N\} \) and particularly (for \( i = N \)) there exists an input \( u_2(.) \) for \( \Delta_2 \) such that

\[
\forall s \in [0, t], \ (u_1(s), u_2(s)) \in \mathcal{H} \text{ and } f(z_1(t), z_2(t)) - f(x_1, x_2) \leq \varepsilon.
\]

\[
\square
\]

**Lemma 7.3.** Let \( x_1 \xleftarrow{t_1} x'_1 \), we define

\[
\text{Post}^H_{t_1}(x_2, x_1 \xleftarrow{t_1} x'_1) = \left\{ x_2' \mid x_2 \xleftarrow{t_2} x'_2 \text{ and for all } s \in [0, t], (u_1(s), u_2(s)) \in \mathcal{H} \right\}
\]

where \( u_i(.) \) is an input which leads \( \Delta_i \) from \( x_i \) to \( x'_i \) at time \( t \) \( (i=1, 2) \). Then, \( \text{Post}^H_{t_1}(x_2, x_1 \xleftarrow{t_1} x'_1) \) is a compact set.

**Proof.** Let us define the set

\[
\text{Post}^t_{t_1}(x_1, x_2) = \left\{ (x'_1, x'_2) \mid x_1 \xleftarrow{t_1} x'_1, \ x_2 \xleftarrow{t_2} x'_2 \text{ and for all } s \in [0, t], (u_1(s), u_2(s)) \in \mathcal{H} \right\}
\]

Let us remark that \( \text{Post}^t_{t_1}(x_1, x_2) \) is the set of reachable points at time \( t \) of a linear system whose input \( u(.) = (u_1(.), u_2(.)) \) is constrained in the compact convex set \( \mathcal{H} \cap (U_1 \times U_2) \). Hence, it can be shown (see e.g. [Aub01]) that \( \text{Post}^t_{t_1}(x_1, x_2) \) is a compact set. Let \( x_1 \xleftarrow{t_1} x'_1 \), then we have

\[
\text{Post}^H_{t_1}(x_2, x_1 \xleftarrow{t_1} x'_1) = \text{Post}^t_{t_1}(x_1, x_2) \cap (\{x'_1\} \times \mathbb{R}^{n_2}).
\]

Hence, it is clear that \( \text{Post}^H_{t_1}(x_2, x_1 \xleftarrow{t_1} x'_1) \) is a compact set. \( \square \)

We can now prove Proposition 3.1. Let \( (x_1, x_2) \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2} \), let \( x_1 \xleftarrow{t_1} x'_1 \). If \( f(x_1, x_2) \geq \eta \), then from Lemma 7.2,

for all \( \varepsilon > 0 \), there exists \( x'_2 \in \text{Post}^H_{t_1}(x_2, x_1 \xleftarrow{t_1} x'_1) \) such that \( f(x'_1, x'_2) \leq f(x_1, x_2) + \varepsilon \).

From Lemma 7.3, \( \text{Post}^H_{t_1}(x_2, x_1 \xleftarrow{t_1} x'_1) \) is a compact subset, moreover \( f \) is a positive \( C^1 \) function and therefore it has closed level sets. Then, from Lemma 2.7, it is clear that

there exists \( x'_2 \in \text{Post}^H_{t_2}(x_2, x_1 \xleftarrow{t_2} x'_1) \) such that \( f(x'_1, x'_2) \leq f(x_1, x_2) \).

Hence, there exists \( x_2 \xleftarrow{t_2} x'_2 \) such that \( f(x'_1, x'_2) \leq f(x_1, x_2) \) and there exist inputs \( u_i(.) \ (i = 1, 2) \) leading \( \Delta_i \) from \( x_i \) to \( x'_i \) at time \( t \) and such that for all \( s \in [0, t], (u_1(s), u_2(s)) \in \mathcal{H} \).
If $f(x_1, x_2) < \eta$, let $v_1(.)$ be an input which leads $\Delta_1$ from $x_1$ to $x_1'$ at time $t$, let $z_1(.)$ the associated trajectory of $\Delta_1$. Let $v_2(.)$ be an input of $\Delta_2$ such that for all $s \in [0, t]$, $(v_1(s), v_2(s)) \in \mathcal{H}$ and $z_2(.)$ the associated trajectory of $\Delta_2$ starting from $x_2$.

If $f(x_1', z_2(t)) \leq \eta$, then we can choose $x_2 \xrightarrow{t} x_2'$ with $x_2' = z_2(t)$. If $f(x_1', z_2(t)) > \eta$, then there exists $s^*$ in $(0, t)$ such that $f(z_1(s^*), z_2(s^*)) = \eta$. Note that $z_1(s^*) \xrightarrow{t-s^*} x_1'$. Since $f(z_1(s^*), z_2(s^*)) = \eta$, we know that there exists $z_2(s^*) \xrightarrow{t-s^*} x_2'$ such that $f(x_1', x_2') \leq f(z_1(s^*), z_2(s^*))$. Moreover, there exist inputs $v_i'(.)$ leading $\Delta_i$ from $z_i(s^*)$ to $x_i'$ ($i = 1, 2$) and such that for all $s \in [s^*, t]$, $(v_1'(s), v_2'(s)) \in \mathcal{H}$. Then, for $i = 1, 2$, let the input $u_i(.)$ be defined by

$$\forall s \in [0, s^*], \quad u_i(s) = v_i(s) \quad \text{and} \quad \forall s \in [s^*, t], \quad u_i(s) = v_i'(s).$$

Then, $u_i(.)$ leads system $\Delta_i$ from $x_i$ to $x_i'$ at time $t$ and for all $s \in [0, t]$, $(u_1(s), u_2(s)) \in \mathcal{H}$ and $f(x_1', x_2') \leq \eta$.
