# From Discrete Specifications to Hybrid Control

## **Abstract**

A great challenge for modern systems theory is the design of controllers for continuous systems but with logical specifications. In this paper, we are interested in developing algorithmic methods which given a discrete time controllable linear system and a discrete specification (in the form of a finite transition system or a temporal logic formula), automatically design controllers resulting in desired, closed-loop behavior. This can be achieved using a natural approach involving three steps. In the first step, given a controllable linear system and discrete specification, we extract a finite transition system model which is equivalent (bisimilar) to the continuous system. The second step solves the controller synthesis problem for finite transition systems using well known and well developed algorithms. The third step, which is the focus of this paper, refines the discrete controller of the finite transition system, to a (necessarily) hybrid controller for the original continuous system. The hybrid controller composed with the continuous plant results in a closed-loop hybrid system that, by construction, satisfies the desired, discrete specification.

## Abstract

A great challenge for modern systems theory is the design of controllers for continuous systems but with logical specifications. In this paper, we are interested in developing algorithmic methods which given a discrete-time controllable linear system and a discrete specification (in the form of a finite transition system or a temporal logic formula), automatically design controllers resulting in desired, closed-loop behavior. This can be achieved using a natural approach involving three steps. In the first step, given a controllable linear system and discrete specification, we extract a finite transition system model which is equivalent (bisimilar) to the continuous system. The second step solves the controller synthesis problem for finite transition systems using well known and well developed algorithms. The third step, which is the focus of this paper, refines the discrete controller of the finite transition system, to a (necessarily) hybrid controller for the original continuous system. The hybrid controller composed with the continuous plant results in a closed-loop hybrid system that, by construction, satisfies the desired, discrete specification.

## 1 Introduction

The invasion of computation and networking inside physical devices has resulted in great challenges for modern and future systems and control theory. Improved understanding and reliable design tools for software controlled systems remain elusive. The greatest technical challenge for our community is understanding the relationship, and mapping properties between the continuous world of control systems, and the discrete world of (programming) languages, automata, and logic.

The above problems very frequently arise when one would like to design a controller for a continuous system

<sup>1</sup>This research is partially supported by NSF Information Technology Research Grant CCR01-21431 and NSF CAREER CCR-01-32716.

but with discrete or logical specifications. Consider, for example, the controllable discrete-time system

$$\Sigma : \quad x(t+1) = Ax(t) + Bu(t)$$

where the desired specification is neither traditional controllability nor stabilizability objectives, but rather a (linear) temporal logic formula  $\phi$ , such as

$$\phi : \square (o_1 \implies \diamond_5 o_2 \vee (\diamond o_3))$$

where  $o_1, o_2, o_3$  are symbols representing regions of the state space of  $\Sigma$  (for example  $o_1$  could denote the set  $(x_1 < -5 \wedge x_2 < -3)$ ),  $\square$  means always;  $\diamond$  means eventually, and  $\diamond_5$  means within five time steps. The desired specification for our example is : it is always the case that if the system visits region  $o_1$  then either the system goes to  $o_2$  within five steps, or, otherwise, must eventually go to region  $o_3$ .

Note that the specification captures both desired continuous behavior but also desired discrete logic. Therefore, controller design for this problem includes designing the software logic in addition to designing the continuous control. Furthermore, note that any controller for the above problem must have at least one bit of memory in order to know whether  $o_1$  has been visited or not. Our goal is to develop algorithmic methods that design controllers for linear systems with respect to temporal logic specifications.

In the computer science community it is well known how to algorithmically translate temporal logic formulas to finite transition systems [16]. We therefore consider the equivalent problem of designing controllers for control system  $\Sigma$  for specifications modeled as finite transition systems. Our approach involves three steps. In the first step (which is the focus of [15]), given controllable system  $\Sigma$  and an observation map, sending continuous states into a finite set of symbols  $O = \{o_1, \dots, o_p\}$ , we construct a finite transition system that is bisimilar to the continuous system. Therefore both the controllable system and the discrete transition system can generate exactly the same sequences of symbols. In the second step, we can use existing methods

and algorithms ([8, 10, 5]) for temporal logic synthesis of finite transition systems. The third step of the approach, which is the focus of this paper, is concerned with mapping the controller designed for the discrete transition system, to a controller for the original continuous system. If the specification is not memoryless, then the controller is necessarily a hybrid system specifying continuous (control) as well as discrete (software, switching logic) information. Furthermore, we show that the hybrid controller composed with the original system indeed satisfy the the desired discrete specification, which is our overall goal.

**Related literature:** Controller synthesis using logic is described in [12] however, logic is not used as a specification mechanism but rather to motivate the development of the synthesis procedures as well as to prove several facts regarding the proposed algorithms. Other synthesis techniques for continuous or hybrid systems with discrete specifications include supervisory control based on approximate finite abstractions [3], invariants for the continuous dynamics [14], convexity properties of affine systems [6], game theoretic approaches [7], and mixed integer linear programming [1]. Language based descriptions of motion have also been considered resulting in motion description languages [2, 9, 4].

## 2 Transition Systems

Transition systems, which we now define, will be the main modeling tool in this paper.

**Definition 2.1** A transition system with observations is a tuple  $T = (Q, Q^0, \longrightarrow, O, H)$ , where:

- $Q$  is a (possibly infinite) set of states,
- $Q^0 \subseteq Q$  is a set of initial states,
- $\longrightarrow \subseteq Q \times Q$  is a transition relation,
- $O$  is a (possibly infinite) set of observations,
- $H : Q \rightarrow O$  is a map assigning to each  $q \in Q$  an observation  $H(q) \in O$ .

We say that  $T$  is finite when both  $Q$  and  $O$  are finite, and infinite otherwise. We will usually denote a pair  $(q, q') \in \longrightarrow$  by  $q \longrightarrow q'$ . The Post operator returns all the states that are one step reachable from a given state, formally we have:

$$\text{Post}(q) = \{q' \in Q : q \longrightarrow q'\}$$

Linear systems can be seen as generating infinite transition systems. Given the discrete-time linear system

$$\Sigma : \quad x(t+1) = Ax(t) + Bu(t)$$

we can define transition system

$$T_\Sigma = (\mathbb{R}^n, \mathbb{R}^n, \longrightarrow_\Sigma, O, H_\Sigma) \quad (2.1)$$

where  $Q = Q^0 = \mathbb{R}^n$ , the state space, and the transition relation is defined as  $x \longrightarrow_\Sigma x'$  iff there exists input  $u \in \mathbb{R}^m$  such that  $x' = Ax + Bu$ . The transition system therefore captures the state dynamics of  $\Sigma$ , without maintaining the input which produced them. Therefore,  $T_\Sigma$  is a slightly more (control) abstract model than  $\Sigma$ . In order to complete the definition of transition system we must also specify the observation map  $H_\Sigma$  and  $O$ . The correct choice of  $O$  and  $H_\Sigma$  is one of the factors enabling the refinement of discrete to hybrid controllers.

Transition systems, with possibly different number of states, can be related by so-called simulation and bisimulation relations. Given a relation  $R \subseteq Q_1 \times Q_2$  we denote by  $R(Q_1)$  the image of  $Q_1$ , that is

$$R(Q_1) = \{q_2 \in Q_2 \mid \exists q_1 \in Q_1 \text{ with } (q_1, q_2) \in R\}$$

and by  $R^{-1}$  we denote the inverse relation defined by:

$$R^{-1} = \{(q_2, q_1) \in Q_2 \times Q_1 : (q_1, q_2) \in R\}$$

**Definition 2.2** Let  $T_1 = (Q_1, Q_1^0, \longrightarrow_1, O, H_1)$  and  $T_2 = (Q_2, Q_2^0, \longrightarrow_2, O, H_2)$  be transition systems and let  $R \subseteq Q_1 \times Q_2$  be a relation. Relation  $R$  is called a simulation relation from  $T_1$  to  $T_2$  if  $R(Q_1^0) \subseteq Q_2^0$ , and  $(q_1, q_2) \in R$  implies:

- if  $q_1 \longrightarrow_1 q'_1$ , then there exists  $q'_2 \in Q_2$  such that  $q_2 \longrightarrow_2 q'_2$  and  $(q'_1, q'_2) \in R$ ,
- $H(q_1) = H(q_2)$ .

Relation  $R$  is a bisimulation relation between  $T_1$  and  $T_2$  if  $R$  is a simulation relation from  $T_1$  to  $T_2$  and  $R^{-1}$  is a simulation relation from  $T_2$  to  $T_1$ .

Note that, in Definition 2.2, we require the observation spaces of  $T_1$  and  $T_2$  to be the same. If  $T_1$  is a transition system with state set  $Q_1$ , then transition system  $T_2$  with state set  $Q_2 \subseteq Q_1$  is called a subtransition system (or subsystem) of  $T_1$  if  $T_1$  simulates  $T_2$  with respect to the inclusion map  $i : Q_2 \rightarrow Q_1$ , that is, the relation  $R = \{(q_2, q_1) \in Q_2 \times Q_1 \mid q_1 = i(q_2)\}$  is a simulation relation.

We now define a composition operator for the class of transition systems that we consider in this paper. In particular, we consider a composition operator that synchronizes the transition systems based on their respective observations.

**Definition 2.3** Let  $T_1 = (Q_1, Q_1^0, \longrightarrow_1, O, H_1)$  and  $T_2 = (Q_2, Q_2^0, \longrightarrow_2, O, H_2)$  be two transition systems with the same observation set  $O$ . The parallel composition of  $T_1$  and  $T_2$  (with output synchronization) is denoted by

$$T_1 \parallel_O T_2 = (Q, Q^0, \longrightarrow, O, H)$$

where

- $Q = \{(q_1, q_2) \in Q_1 \times Q_2 : H_1(q_1) = H_2(q_2)\};$
- $Q^0 = \{(q_1, q_2) \in Q_1^0 \times Q_2^0 : H_1(q_1) = H_2(q_2)\};$
- $(q_1, q_2) \longrightarrow (q'_1, q'_2)$  for  $(q_1, q_2), (q'_1, q'_2) \in Q$  iff  $q_1 \longrightarrow_1 q'_1$  and  $q_2 \longrightarrow_2 q'_2$ ;
- $H(q_1, q_2) = H_1(q_1) = H_2(q_2).$

Our controller synthesis problem is the following : Given continuous plant  $\Sigma$ , its corresponding infinite transition system  $T_\Sigma$ , and discrete specification  $T_S$ , design controller  $T_C$  such that  $T_C \parallel_O T_\Sigma$  is simulated by the specification  $T_S$ . Therefore the closed loop behavior is captured by the desirable behavior. This is performed in three steps. In the first step, described in Section 3, given a continuous linear system  $\Sigma$  we show how to extract a finite transition system  $T_\Delta$  that is bisimilar to  $T_\Sigma$ . The second step, described in Section 4, we show that controllers for  $T_\Delta$  exist if and only if controllers for  $T_\Sigma$  exist. Finally, in Section 5, we show how to construct the closed loop system for  $T_\Sigma$ , given designed discrete controllers for  $T_\Delta$ .

### 3 From the continuous to the discrete

In this section, we summarize the results obtained in [15], which are utilized in this paper. Consider a discrete time controllable linear system:

$$\Sigma : x(t+1) = Ax(t) + Bu(t)$$

Controllability guarantees the existence of a feedback transformation:

$$\begin{bmatrix} y \\ v \end{bmatrix} = U \begin{bmatrix} x \\ u \end{bmatrix} = \begin{bmatrix} F & \mathbf{0}_{n \times m} \\ G & H \end{bmatrix} \begin{bmatrix} x \\ u \end{bmatrix} \quad (3.1)$$

transforming system  $\Sigma$  into Brunovsky normal form [13]. This transformation incorporates important system information that will be used in this section as well as in Section 5. Associated with  $\Sigma$  is the infinite transition system  $T_\Sigma$  described in (2.1):

$$T_\Gamma = (\mathbb{R}^n, \mathbb{R}^n, \longrightarrow_\Sigma, O, H_\Sigma)$$

To obtain a finite bisimulation of  $T_\Sigma$  we consider a finite set of observations  $O$ . Observations will correspond

to subsets of  $\mathbb{R}^n$  defined by boolean combinations of predicates of the form:

$$fx + c \sim 0 \quad (3.2)$$

where  $f$  is a row of matrix  $F$ ,  $c \in \mathbb{Q}$  and  $\sim \in \{<, \leq, =, \geq, >\}$ . Given  $p$  such predicates we define the observation space to be  $\{0, 1\}^p$  and the observation map as:

$$H_\Sigma(x) = \begin{bmatrix} H_{\Sigma 1}(x) \\ H_{\Sigma 2}(x) \\ \vdots \\ H_{\Sigma p}(x) \end{bmatrix} \quad H_{\Sigma i} = \begin{cases} 1 & \text{if } f_i x + c_i \sim_i 0 \\ 0 & \text{if otherwise} \end{cases} \quad (3.3)$$

The vector  $H_\Sigma(x)$  will then have a 1 at position  $i$  when state  $x$  satisfies the predicate  $f_i x + c_i \sim_i 0$  and a 0 otherwise. The main result of [15] can now be stated as follows:

**Theorem 3.1** ([15]) *Let  $\Sigma$  be a discrete time controllable linear system and  $T_\Sigma$  its associated infinite transition system with observation space  $O = \{0, 1\}^p$  and observation map as defined in (3.3). Then, there exists an effectively computable finite transition system  $T_\Delta$ , bisimilar to  $T_\Sigma$ .*

The bisimulation relation between  $T_\Sigma$  and  $T_\Delta$  is in fact defined by a map  $\pi : \mathbb{R}^n \rightarrow Q_\Delta$ , that is  $R = \{(x, q) \in \mathbb{R}^n \times Q_\Delta : \pi(x) = q\}$ . More details regarding the construction of relation  $R$  and transition system  $T_\Delta$  can be found in [15].

In this paper, we are interested in designing controllers for  $T_\Sigma$ , where the desired specification is modeled by a finite transition system with observation space  $O = \{0, 1\}^p$ . Such transition systems can be translations of temporal logic formulas, such as LTL (see [16]) formulas, or they can be high level specifications for the desired closed loop behavior expressed directly in transition system form. We denote such a specification transition system by  $T_S$  and we will assume that the observation space of  $T_S$  is the observation space of the plant.

### 4 Discrete Controllers

A controller forcing our discrete model  $T_\Delta$  to satisfy the specification given by  $T_S$  can now be defined.

**Definition 4.1 (Discrete Controller)** *Let  $T_\Delta$  be the transition system described in Theorem 3.1, and let  $T_S$  be a transition system with the same observation space, modeling the desired specification.*

A controller for  $T_\Delta$ , denoted by  $T_C$ , is a subtransition system of  $T_S \parallel_O T_\Delta$ , that is,  $T_S \parallel_O T_\Delta$  is a simulation of  $T_C$  with respect to the inclusion map.

We now show in what sense  $T_C$  can be seen as a controller.

**Proposition 4.2** *Transition system  $T_S$  is a simulation of transition system  $T_C \parallel_O T_\Delta$ .*

The existence of a simulation from  $T_C \parallel_O T_\Delta$  to  $T_S$  implies that the observed behavior of  $T_C \parallel_O T_\Delta$  is included in the observed behavior of the specification. We also note that we can choose our controller to be  $T_C = T_S \parallel_O T_\Delta$ , however  $T_S \parallel_O T_\Delta$  may fail to satisfy certain important properties usually required by a controller, such as nonblocking for example. Such a drawback can be incorporated in the control design by selecting a subtransition system of  $T_S \parallel_O T_\Delta$  with the desired (say nonblocking) properties. Proposition 4.2 is a consequence of the following two lemmas:

**Lemma 4.3** *Transition system  $T_C$  is bisimilar to transition system  $T_C \parallel_O T_\Delta$ .*

**Proof:** Consider the relation  $R \subseteq (Q_S \times Q_\Delta) \times ((Q_S \times Q_\Delta) \times Q)$  defined by  $((q_S, q_\Delta), ((q'_S, q'_\Delta), q''_\Delta)) \in R$  iff  $q_\Delta = q'_\Delta = q''_\Delta$  and  $q_S = q'_S$ . We first show that  $T_C \parallel_O T_\Delta$  simulates  $T_C$ . Assume that  $(q_S, q_\Delta) \xrightarrow{C} (q'_S, q'_\Delta)$  and note that this implies  $q_\Delta \xrightarrow{\Delta} q'_\Delta$ . Consider now any state  $R$ -related to  $(q_S, q_\Delta)$ . By definition of  $R$ , such state is of the form  $((q_S, q_\Delta), q_\Delta)$  and by definition of parallel composition, we have that  $(q_S, q_\Delta) \in Q_C \Rightarrow H_C(q_S, q_\Delta) = H_\Delta(q_\Delta) = H_{\parallel_O}((q_S, q_\Delta), q_\Delta)$ . Similarly  $H_C(q'_S, q'_\Delta) = H_\Delta(q'_\Delta) = H_{\parallel_O}((q'_S, q'_\Delta), q'_\Delta)$  holds. These equalities between observation maps combined with  $(q_S, q_\Delta) \xrightarrow{C} (q'_S, q'_\Delta)$  and  $q_\Delta \xrightarrow{\Delta} q'_\Delta$  now imply that  $((q_S, q_\Delta), q_\Delta) \xrightarrow{\parallel_O} ((q'_S, q'_\Delta), q'_\Delta)$  which shows that  $T_C \parallel_O T_\Delta$  simulates  $T_C$ .

Conversely, let's assume that  $((q_S, q_\Delta), q_\Delta) \xrightarrow{\parallel_O} ((q'_S, q'_\Delta), q'_\Delta)$ . Such transition implies that  $(q_S, q_\Delta) \xrightarrow{C} (q'_S, q'_\Delta)$  and since any state  $R$ -related to  $((q_S, q_\Delta), q_\Delta)$  is of the form  $(q_S, q_\Delta)$  we only need to show that  $H_{\parallel_O}((q_S, q_\Delta), q_\Delta) = H_C(q_S, q_\Delta)$  and  $H_{\parallel_O}((q'_S, q'_\Delta), q'_\Delta) = H_C(q'_S, q'_\Delta)$  to conclude that  $T_C$  simulates  $T_C \parallel_O T_\Delta$ . However this immediately follows from the definition of parallel composition with output synchronization. ■

**Lemma 4.4** *Transition system  $T_S$  simulates transition system  $T_C$ .*

**Proof:** The proof follows the same argument as the proof of Lemma 4.3 once one considers the relation  $R \subseteq Q_C \times Q_S$  defined by  $(q_C, q'_S) = ((q_S, q_\Delta), q'_S) \in R$  iff  $q_S = q'_S$ . ■

We now show that a controller  $T_C$  for  $T_\Delta$  exists if and only if a controller  $T'_C$  for  $T_\Sigma$  exists. This is a consequence of the existence of a bisimulation relation between  $T_\Sigma$  and  $T_\Delta$ .

**Theorem 4.5** *A controller  $T_C$  forcing system  $T_\Delta$  to satisfy specification  $T_S$  exists iff there exists a controller  $T'_C$  forcing system  $T_\Sigma$  to satisfy specification  $T_S$ . Furthermore, we can take  $T_C = T'_C$ .*

This theorem is a simple consequence of the following well known property of bisimulations and Proposition 4.2.

**Proposition 4.6 (Adapted from [11])** *Let  $T_1$  and  $T_2$  be transition systems with the same observation space. If  $T_1$  is bisimilar to  $T_2$  then, for any transition system  $T$  with the same observation space,  $T \parallel_O T_1$  is bisimilar to  $T \parallel_O T_2$ .*

The proof of Theorem 4.5 is now a simple application of the previous proposition. Given transition systems  $T_1$  and  $T_2$ , we denote by  $T_1 \cong T_2$  the existence of bisimulation relation between  $T_1$  and  $T_2$ . We now have  $T_\Sigma \cong T_\Delta$  from which follows  $T_C \parallel_O T_\Sigma \cong T_C \parallel_O T_\Delta$  by Proposition 4.6. Now since  $T_S$  simulates  $T_C \parallel_O T_\Delta$  it also simulates  $T_C \parallel_O T_\Sigma$  which shows that  $T_C$  is a controller for  $T_\Sigma$ .

Existence of controllers is therefore ensured, however  $T_C$  is an abstract (discrete) description of our controller. In the next section we refine our controller from the discrete system  $T_\Delta$  to the continuous system  $T_\Sigma$ .

## 5 From the discrete to the continuous

Given any controller  $T_C$ , we now construct a (discrete-time) hybrid control system  $H$  based on  $\Sigma$  and  $T_C$  such that the transition system  $T_H$  associated with  $H$  is bisimilar to  $T_C \parallel_O T_\Sigma$ . We start by characterizing the set of inputs for the linear system  $\Sigma$  associated with a given transition in  $T_\Delta$ . We denote by  $[q]$  the set of all points  $x \in \mathbb{R}^n$  such that  $\pi(x) = q$  (the map  $\pi$  defines the bisimulation relation between  $T_\Sigma$  and  $T_\Delta$  as discussed in Section 3). This set is defined by boolean combinations of predicates of the form  $\phi_i = f_i x + c_i \sim_i 0$ ,  $i \in I$ . The predicates  $\phi_i$  and the map  $\Xi$  defined by

$$\Xi(\phi_i) = \text{True}$$

when  $i \notin \{k_1, k_1 + k_2, \dots, k_1 + k_2 + \dots + k_r\}$  and

$$\Xi(\phi_i) = g_j x + h_j u + c_i \sim_i 0$$

when  $i = k_1 + k_2 + \dots + k_j$  and where  $g_j$  and  $h_j$  are the rows of matrices  $G$  and  $H$  defined in (3.1), respectively, will be instrumental in stating the next result:

**Proposition 5.1** *Let  $T_\Delta$  be the finite bisimilar quotient of transition system  $T_\Sigma$  associated with a discrete time controllable linear system  $\Sigma = (A, B)$ . If  $q_\Delta \rightarrow_\Delta q'_\Delta$  in  $T_\Delta$  and  $[q'_\Delta]$  is defined by:*

$$[q'_\Delta] = \left\{ x \in \mathbb{R}^n : \bigvee_{r \in R} \bigwedge_{s \in S_r} \phi_{rs}(x) \right\} \quad (5.1)$$

then, the inclusion  $Ax + Bu \in [q'_\Delta]$  is satisfied for any  $x \in [q_\Delta]$  iff  $(x, u) \in \mathcal{A}(q_\Delta, q'_\Delta)$  with  $\mathcal{A}$  defined by:

$$\mathcal{A}(q_\Delta, q'_\Delta) = \left\{ (x, u) \in [q_\Delta] \times \mathbb{R}^m : \bigvee_{r \in R} \bigwedge_{s \in S_r} \Xi(\phi_{rs})(x, u) \right\} \quad (5.2)$$

**Proof:** Assume, without loss of generality, that  $\Sigma$  has been transformed into Brunovsky normal form. From  $q_\Delta \rightarrow_\Delta q'_\Delta$  and bisimilarity between  $T_\Delta$  and  $T_\Sigma$  follows that any  $y \in [q_\Delta]$  satisfies:

$$y \rightarrow_\Sigma y' \in [q'_\Delta] \quad (5.3)$$

Furthermore, from the Brunovsky form of  $\Sigma$ , (5.3) holds iff the inputs  $v$  satisfy:

$$v_j = y'_{k_1+k_2+\dots+k_j} \quad (5.4)$$

for  $j = 1, 2, \dots, m$ . Since  $y' \in [q'_\Delta]$ ,  $y'$  satisfies the predicates in (5.1) and from (5.4) we conclude that  $v$  satisfies all the predicates  $\phi_{rs}$  defining  $[q'_\Delta]$  such that  $\phi_{rs} = y'_{k_1+k_2+\dots+k_j} + c \sim 0$ . Noting that the transformed inputs  $v$  are obtained from the original states  $x$  and inputs  $u$  by  $v = Gx + Hu$  we immediately see that:

$$\begin{aligned} y'_{k_1+k_2+\dots+k_j} + c &= v_j + c \\ &= w_j v + c \\ &= w_j(Gx + Hu) + c \\ &= w_j Gx + w_j Hu + c \\ &= g_j x + h_j u + c \end{aligned}$$

where  $w_j$  is the row vector with a 1 on position  $j$  and zeros elsewhere. We thus see that for any  $x \in [q_\Delta]$  we have that  $Ax + Bu \in [q'_\Delta]$  iff  $(x, u) \in \mathcal{A}(q_\Delta, q'_\Delta)$ . ■

Having identified the set of inputs associated with any transition in  $T_\Delta$ , we can control  $\Sigma$  by restricting its inputs. Such restriction is captured in the following hybrid closed loop model:

**Definition 5.2** *Given a controllable discrete-time linear system  $\Sigma = (A, B)$  and a controller  $T_C = (Q_C, Q_C^0, \rightarrow_C, O, H_C)$ , the implementation of  $T_C \parallel_O T_\Sigma$  is given by the hybrid closed loop system  $H$  defined by:*

$$\begin{aligned} x(t+1) &= Ax(t) + Bu(t) \\ (x(t), u(t)) &\in \widehat{\mathcal{A}}(q_C(t)) \\ q_C(t+1) &\in H_C^{-1} \circ H_\Sigma(x(t+1)) \end{aligned}$$

where

$$\widehat{\mathcal{A}}(q_C(t)) = \bigcup_{q'_C \in \text{Post}(q_C(t))} \mathcal{A}(\pi_\Delta(q_C(t)), \pi_\Delta(q'_C))$$

and  $\pi_\Delta : Q_S \times Q_\Delta \rightarrow Q_\Delta$  is the natural projection from  $Q_S \times Q_\Delta$  to  $Q_\Delta$ .

Associated to hybrid system  $H$  is the transition system  $T_H = (Q_H, Q_H^0, \rightarrow_H, H_H, O)$  defined by:

- $Q_H = Q_C \times \mathbb{R}^n$ ;
- $Q_H^0 = \{(q, x) \in Q_C^0 \times \mathbb{R}^n : H_C(q) = H_\Sigma(x)\}$ ;
- $(q_C, x) \rightarrow_H (q'_C, x')$  iff  $x' = Ax + Bu$ ,  $(x, u) \in \widehat{\mathcal{A}}(q_C)$  and  $H_C(q') = H_\Sigma(x')$ .
- $H_H(q_C, x) = H_C(q_C) = H_\Sigma(x)$ .

Transition system  $T_H$  allows to show that the closed loop hybrid system  $H$  is in fact an implementation of the closed loop behavior described by  $T_C \parallel_O T_\Sigma$ .

**Proposition 5.3** *Transition system  $T_H$  is bisimilar to  $T_C \parallel_O T_\Sigma$ .*

**Proof:** Consider the relation  $R \subseteq Q_H \times (Q_S \times Q_\Delta)$  defined by  $(q_H, (q_S, q_\Delta)) = ((q_C^0, x), (q_S, q_\Delta)) = (((q'_S, q'_\Delta), x), (q_S, q_\Delta)) \in R$  iff  $(q'_S, q'_\Delta) = (q_S, q_\Delta)$ . The proof now follows the same argument as the proof of Lemma 4.3. ■

Proposition 5.3 shows that  $H$  constitutes the desired closed loop system since  $T_C \parallel_O T_\Delta$  being bisimilar to  $T_H$  and  $T_C \parallel_O T_\Delta$  satisfying the desired discrete specification  $T_S$  implies that  $T_H$  also satisfies the specification. Furthermore, as every step in the construction of  $H$  is effectively computable we have the following result:

**Theorem 5.4** *Let  $\Sigma$  be a discrete time controllable linear system,  $T_\Sigma$  its associated transition system with observation space  $O = \{0, 1\}^p$  and observation map as*

defined in (3.3) and  $T_S$  a specification transition system. Then, it is decidable to determine if there is a controller for  $\Sigma$  enforcing the specification  $T_S$ . Furthermore, when such controller exists, it admits the hybrid closed loop implementation described by  $H$  which is effectively computable.

**Proof:** Deciding the existence of a controller for  $\Sigma$  amounts to determine if the observed behavior of  $T_S \parallel_O T_\Delta$  is non-empty which is decidable. Furthermore, since  $H$  is obtained from  $T_C$  by enriching the states of  $T_C$  with the finite predicates defining  $\hat{A}$ ,  $H$  is also effectively computable. ■

The previous result summarizes the paper main contributions. Existence of controllers for discrete specifications can be decided. Furthermore, when a controller exists it admits a hybrid closed loop implementation that can be obtained in a totally automated fashion. Another important characteristic of the presented method is the automatic synthesis of both the switching logic (implemented by software) and the continuous aspects of control. This fact is especially important since verification of hybrid systems is currently limited to systems with very simple continuous dynamics such as timed automata. The proposed approach, thus overcomes the need for formal verification since the resulting system satisfies the specification by design.

## 6 Discussion

In this paper we have shown how to design controllers enforcing discrete specifications for discrete time controllable linear systems. The synthesis procedure relied on the computation of a finite bisimulation of the original plant as described in [15]. A finite controller is first computed for the finite model and subsequently refined to an hybrid closed loop. The proposed synthesis methodology thus generates the switching logic stemming from the discrete specification as well as the continuous inputs that are admissible to steer the system while satisfying the specification.

The presented results suggest a framework for the automatic synthesis of controllers for temporal logic specifications by converting logic formulas into discrete specifications in the form of transition systems. Furthermore, the algorithmic nature of the approach also suggests the complete automation of controller synthesis which is currently being investigated by the authors.
