Typologizing the sociolinguistic speech community
Typologizing the Sociolinguistic Speech Community

Otto Santa Ana and Claudia Parodi

1. Introduction and the Mexican Setting

We propose a comprehensive hierarchical model of SPEECH COMMUNITY which can be applied to fieldwork research in both urban and non-urban domains. We focus on dialect contact in order to describe Spanish dialect distribution in contemporary Mexico as this ranges from provincial and regional Mexican Spanish to standard Mexican Spanish. The Michoacán Bajío is the region of our research.

Michoacán has coastline on the Pacific Ocean and is part of the western altiplano of Mexico. It is around the mid-way point of Mexico traveling north and south. One of the cities of the Bajío is Zamora, the pivot point for our study. Zamora is a regional hub of agriculture and commerce. Circling Zamora are a set of smaller towns numbering less than 40,000 people, communities of about 10,000 people, small villages and even smaller ranchos inhabited by one or two families of farmers.

2. Our Project and Findings

Our investigation involved gathering 50 hours of vernacular Mexican Spanish from a broad sample of 35 native speakers of the Zamora region of Michoacán. This data was collected with a protocol, which is in keeping with the multiple methods laid out in Labov (1984) It included sociolinguistic interviews, a battery of tests to investigate language use in different genres as well as at different levels of formality, and a series of language attitude tests. The interviews gave the impression of being informal conversation, but in fact we followed covertly structured guidelines. At times both authors interviewed a single informant, to sample a wider range of the informant’s interactional responses. We also attempted to draw the individual interviewee into group conversation.

A sequence of genre, formality and attitude tests were devised to investigate other knowledge of Spanish varieties. Subjunctive constructions were tested, hypothetical constructions were sought out. Levels of formality were tested with role-playing exercises and humorous narrated skits that were pre-recorded. Decontextualized sentence pairs were presented, again to test evaluation of alternating variables. Next we asked the interviewees to compare a pair of formal and informal letters. We lastly asked a series of questions on language use and judgments. From all this data we found: different variable use patterns among different groups of Mexican Spanish speakers, and different patterns of linguistic evaluation among different groups of these speakers, based on both local (vernacular) and non-local Mexican Spanish. Moreover, some individuals demonstrated no apparent awareness of the social evaluation patterns of language variation at all. These findings indicate that more than one speech community comprise the Zamora region.

3. A Speech Community Typology

In our model, the shared evaluation of linguistic variables is critical. Socially marked linguistic features delimit speech communities. These features, however, do not mark out mutually exclusive grouping of speakers. In our proposal, speech communities can be seen to be arranged in sets of multiply embedded groupings of individual speakers as schematized in Figure 1.

Figure 1: Speech communities schematic

In this model each speech community of Mexico is distinguished and defined in terms of binary [±] features. At the center of the model is the speaker’s recognition that there is a linguistic hierarchy that reflects the social hierarchy in which he/she has a position. Recognition that there is a social hierarchy,
minimal. Contacts with the socializing and evaluative social institutions which strongly affect people's sense of self and their speech, such as schooling or work outside of the home, have been tenuous and brief. Other contacts with the larger social world are superficial, such as the passive reception of radio and television emissions. Consequently the influence of the language of the larger social environment in like manner is limited.

In the language use of the nuclear field speakers, we note a usage distinction between stigmatized words and taboo words. Stigmatized words which have no taboo content, such as non-standard *mesmo* 'same', as opposed to standard *mismo*, will not be recognized by nuclear field speakers. Likewise stigmatized pronunciations, such as a velar aspirated pronunciation of the standard /l/ in initial position of certain words are used by these speakers, with no sense that there is any proscription against this usage. Examples include *fiiera* 'outside' or *herrar* 'to shoe horses' pronounced [xhiera] and [xherar] instead of the standard pronunciation [fiera] and [errar]. On the other hand lexical items which have taboo semantic content, such as *puta* 'whore', will be recognized as a stigmatized item. Such words will be used or avoided, according to the social circumstance.

### 3.2. Locale Field

Locale field speakers recognize that the social hierarchy is expressed in linguistic variation, in terms of a standard–nonstandard opposition. These speakers are aware of their limited knowledge of the hierarchy, but they show knowledge of some stigmatized features. Locale field speakers register insecurity about their ways of speaking, and demonstrate some evaluative judgment of the ways that others speak.

---

2 The stigmatized words in Mexican Spanish are 16th century lexical items which were part of the vernacular Spanish of the first settlers of the Americas. Many, such as *haiga* and *ansina/ansina* are located throughout the non-metropolitan New World (e.g., Cárdenas 1967; Rona 1973:319). These items were subsequently replaced in Latin American cities, such as Mexico City. Since there was greater interaction across metropolitan areas in Latin America, than between Mexico City and its provinces, these items are stigmatized across Latin America by metropolitan speakers. Because the provinces did not replace them, they are labeled as rural ways of speech.

These speakers recognize taboo words and variably use them as befitting the social setting. Non-taboo stigmatized *mesmo* and *ansa* forms are still used over the standard *mismo* 'same' and *ans* 'in this way' forms, but there is some awareness of the stigmatized value of particular lexical items. However, most phonological features that are stigmatized by wider field speakers may remain unknown to the locale field speakers. That is, they are aware of the existence of a hierarchy, but they do not identify all the items that constitute the stigmatized features of Mexican Spanish.

The life ways of locale field speech communities involve greater social intercourse with local and regional communities. At the locale field, recognition of the social hierarchy represents an imposition on the individual of the social values of the larger local and regional world. This does not imply the automatic use of the linguistic features associated with the wider speech community values.

Locale field individuals are not tacitly knowledgeable about the full set of stigmatized lexical items of the region. In our sample their contact with the wider world became regular only during adult life. Commodity labor, which only supplements their subsistence economy, provides limited exposure to the ways of speaking in the regional world. Schooling, which is the prime socializing setting for exposure to the full set of proscribed lexical items, is not a significant part of these individuals' life history. Locale field people are more sensitive about the way they speak with outsiders. When asked to evaluate their own speech, they provide ambivalent answers. In our model this field refers to a set of families which comprise a social network. The key here is that each individual in the locale knows the other, not as a casual acquaintance but as someone whose life impacts the speaker.

### 3.3. District Field

In this speech community configuration speakers demonstrate recognition of a stable set of stigmatized features. These features include the lexical, phonological and syntactic items that are generally stigmatized by national field Mexican (and possibly all Latin American) standard Spanish speakers. Assignment to this speech community configuration will not necessarily require that individuals have complete productive control of these features, or that they generally opt to use non-stigmatized forms over
stigmatized forms. Non-standard speakers are aware of the hierarchy, and the stigmatized forms that constitute it, yet they continue to use stigmatized forms, even if they may believe that they never use them.

District field speakers use the non-standard regional dialect. They show themselves to range from quite secure to insecure about the way that they speak, and how they are judged; they judge themselves as inferior speakers of their native language. Further, they judge their non-standard speech to be a personal limitation and do not see their speech to be representative of wider regional patterns.

District field speakers have attended some years of elementary school. They are involved in a wider public sphere than locale field speakers. Social interaction involves activity in a public sphere among non-acquaintances. In our sample these people own small businesses, and they interact in market activities with people who represent a wide set of social groups and various economic classes, yet they may not have lived in regions of Mexico beyond the Bajío.

3.4. Regional Field

At the regional field individuals are aware of the set of stigmatized items, which they tend not to use. These individuals are cognizant that they speak a regional accent, which is called a tiple [tiple]. The tiple is not used as a derogation. For Bajío residents, it means 'regional accent', which they identify with their area of origin. This may or may not lead the individual to believe that there are other regional accents. It may be that recognition of one's tiple is seen as a marked dialect, opposed to the unmarked standard Mexican Spanish. However, as the individual's life ways provide him/her with acquaintances and contacts from a wider range of Mexican people, knowledge of a range of regional dialects can be developed.

3.5. National Field

At the national speech community configuration, individuals are fully cognizant of the regional features of their home region, but they infrequently use them. They prefer standard forms. They may not want to acknowledge any ability to use such features, when asked directly. Some national field individuals consider certain marked regional pronunciations to be non-standard, but these features are not stigmatized. A mild version of the regional pronunciation features might be used by standard Mexican Spanish speakers as indicators of casual and intimate speech.

They are fully aware of the social hierarchy and their privileged place. The judgment of such individuals usually is that non-standard speakers (from nuclear to regional) are regrettably "limited" by their pronunciation and ignorance of the single "correct" way of speaking. This is particularly apparent in certain strata of Mexican society which is most influenced by its language academy tradition. As people at the top of the social hierarchy, these national field speakers tend to be in positions of power to impose their biases on their hierarchical subordinates.

4. Michoacán Spanish Elements of the Typology

In this section we address the main varieties of Spanish upon which this typology is drawn: stigmatized; regional Mexican; and standard Mexican Spanish.

Stigmatized Spanish is constituted by lexical, phonological and morphological remnants of the old American Spanish koine that was formed in the New World during the 16th century (see Cárdenas 1967; Parodi 1995:39) Native speakers are not aware of the fact that stigmatized forms are residues of the old koine. They simply label them as rural or uneducated speech. In school, for example, these forms are censured. Since they reflect parts of an older stage of Latin American Spanish language, the features are not peculiar to Michoacán and are found in other areas of Mexico and Latin America where they are stigmatized among speakers of district, region and national fields. The following words, as used by our Bajío informants, exemplify stigmatized speech: fueron [xhweron] 'they went', asegun, 'according to', padr 'wall', asina or ansina 'this way', probe 'poor', bia 'there was', naiden 'no one', haiga 'there is', mesma 'the same', aigre 'air', etc.

Regional Mexican Spanish is composed of lexical and phonological items that are recognized by Mexican speakers as identifying native speakers of a certain region. The features are not stigmatized, rather they are indicators of the native region of a speaker in the sense of Labov (1972) Some of the regional features characteristic of Michoacán are also found in other areas of Mexico and Latin America. What distinguishes Michoacán speakers from the speakers of the other areas is the use of a specific set of
features. Some of these features are the following: close vowels, for example calle [kayi] ‘street’, pocos [pokus] ‘few’, weakening of /lj/ and /tl/, as exemplified by caballo [kabaju] ‘horse’ and leche [leji] ‘milk’. We heard discursive forms, including a nasal off-glide after /s/. Thus, pues ‘well then’ is variably pronounced [puesN]. There is also the form [ey] with a high rising intonation, which is used in conversation as a sublexical acknowledgment, approval, or simply to say ‘yes’. Further, there is a particular set of intonational patterns, for which people of the region have a term we have mentioned earlier, a tiple (see also Cárdenas 1967, Moreno de Alba 1988).

Standard Mexican Spanish, as any standard variety, is regarded as the form of speech of educated speakers. It is taught in schools, and it is used in the written texts throughout Mexico. The Mexican standard is a variety of Modern Spanish. That is, Mexican standard Spanish has certain features that are accepted by educated Spanish speakers throughout the Hispanic world. Some of these features include: seseo, or the lack of the opposition between /s/ and the voiceless interdental fricative; yeismo, or the lack of the opposition between the palatal lateral and /l/; the use of the pronoun ustedes for formal and informal speech, since the pronoun vosotros for the informal second person has been lost; peculiar use of the preposition hasta ‘since’, etc.

5. Conclusion

We proposed a typology of speech communities in five fields from most local to most expanded configuration. Our typology is a comprehensive model of speech communities that utilizes Labov’s (1972) shared linguistic evaluation criterion, and the notions of linguistic hierarchy; stigmatized linguistic feature; regional linguistic feature; and, standard linguistic features. No other mechanisms are posited to motivate the model, which is an attempt to describe the various language settings of a non-metropolitan community. It is also a typology that may be extended to all speech communities to characterize the different relationships that individuals can have in communities.

Symbolic Identity and Language Change:
A Comparative Analysis
of Post-Insular /ay/ and /aw/

Natalie Schilling-Estes and Walt Wolfram

1. Introduction

The study of moribund dialects on the Outer Banks of North Carolina over the past few years (e.g., Wolfram and Schilling-Estes 1995; Schilling-Estes 1996; Wolfram and Schilling-Estes 1996, Wolfram, Hazen, and Schilling-Estes forthcoming) has tempted us to assume that a generalized model of dialect recession might apply to receding dialects. Our study of dialect change on the island of Ocracoke, North Carolina, supported for the most part a DISSIPATION MODEL, in which traditional dialect features are simply lost or drastically eroded in the post-insular state of an historically isolated variety. The examination of another post- insular Outer Banks island community, Harkers Island (Cheek 1995; Wolfram, Cheek, and Hammond 1996) supported the dissipation model, allowing for minor changes in the regression slope of erosion. It is important, however, to challenge the assumptions of the dissipation model based on a variety of different post-insular dialect situations. Therefore, in this investigation, we examine a quite different post-insular community, Smith Island, Maryland. Our examination will demonstrate that there may be significant diversity in how post-insular dialects recede. In fact, we show that the moribund state of some language varieties may be characterized by a CONCENTRATION MODEL of dialect recession in which features actually intensify rather than dissipate as the variety dies.

Several of our previous discussions have focused on the well-known production of /ay/ with a raised and backed nucleus [\^\textcircled{a}] in Ocracoke English (Wolfram and Schilling-Estes 1995, 1996; Schilling-Estes 1996). In this investigation, we focus on the production of /ay/ in Smith Island, which is realized with a raised, centralized nucleus, and compare it with the Ocracoke raised and backed variant. We also investigate the patterning of the /aw/ diphthong, the back upgliding diphthong that parallels front upgliding /ay/. As we shall see, /aw/ may be realized with a raised and/or fronted nucleus as well as a fronted glide in both Ocracoke and Smith Island.

The data from Smith Island are drawn from a set of cross-generational sociolinguistic interviews with 42 islanders conducted by Rebecca Setliff in the early 1980s, while the Ocracoke data are drawn from the 70-plus interviews we have collected there to date, beginning in the early 1990s. Figure 1 shows the locations of Ocracoke and Smith Island in relation to each other.

Smith Island is located in the Chesapeake Bay, about 10 miles from the mainland Delmarva Peninsula. Like Ocracoke, which is located 20 miles from the mainland of North Carolina, Smith Island has been accessible only by boat since its first British inhabitants settled there in the latter half of the 1600s. Although both islands have historically been isolated from mainland communities, they are currently undergoing significant social and economic change. The characteristics of each island's transformation are summarized in (1) and (2) below.

(1) The Socioeconomic Transformation of Ocracoke

- Two and a half centuries of geographic isolation are brought to a sudden end in the 1950s with the implementation of a state-run ferry service and the construction of a paved highway that runs the length of the island.
- Ancestral islanders (approximately 350) become a minority population on the island, as tourists from the mainland vacation there, and other mainlanders establish permanent and vacation residences on the island. Currently, approximately 3,000 to 5,000 tourists per day visit Ocracoke during the tourist season, while 400 mainlanders have set up homes on the island.
- The economic base shifts from a relatively self-sufficient marine-based economy to one heavily dependent on the tourist trade.
- Social networks extend beyond the confines of the island as Ocracokers come into more contact with outsiders: marriage with mainlanders becomes more commonplace, as do working and other social relationships.

(2) The Socioeconomic Transformation of Smith Island

- The land mass of the island shrinks significantly, at a rate of over 1,000 acres of loss in less than a century.
- The population declines significantly, from almost 700 in 1960 to about 450 in 1990.
- Traditional occupations such as crabbing and oystering decline, forcing islanders to move off the island to seek alternative means of sustenance.
- Tourism is a minor trade, and there is little in-migration.
- Social networks are restricted for islanders who continue to live on the island.

A couple of noteworthy contrasts are found in the Smith Island and Ocracoke situations, including the nature of the population shifts, socioeconomic changes and alterations to interactional networks affecting each community. Over the past several decades, Smith Island has lost over a third of its population as its marine-based economy declines, thus forcing islanders to seek work on the mainland. Meanwhile, Ocracoke has grown steadily as its traditional marine-based economy is supplanted by tourism. Regular interaction between outsiders and islanders is quite limited on Smith Island, whereas the expanding service-based industry on Ocracoke is characterized by increased intermingling between outsiders and Ocracokers. The differential sociohistorical and socioeconomic situations lead us to ask obvious questions regarding the process of language change in these two communities: How is language change proceeding in these two island communities? What can a comparison of these two situations tell us about generalized models of language recession? How do linguistic and sociocultural factors converge in the
explication of principles of language change and recession?

In the following sections, we consider these questions by examining two diagnostic diphthongs in Smith Island and Ocracoke, namely /ay/ and /aw/. The variable patterning of each of these diphthongs is changing in each community in significant but different ways. The explanation for their differential diachronic patterning is not reducible to a simple matter of linguistic process or sociohistorical circumstance. Instead, our explication demonstrates how linguistic principles and sociocultural factors intersect to account for patterns of dialect change and recession.

2. The Contrasting Directionality of /ay/

Our previous studies of dialect recession in Ocracoke English indicated that a number of traditional dialect features, including raised, backed /ay/, have receded rather dramatically over the course of the past several generations (Wolfram and Schilling-Estes 1995; Schilling-Estes 1996). How does this recession compare with the patterning of /ay/ on Smith Island, where /ay/ may be realized with a raised nucleus as well? Results of our comparative quantitative analysis of the diachronic and synchronic patterning of raised /ay/ in Ocracoke and Smith Island are summarized in Tables 1 and 2. Raw percentages for the incidence of the raised variant of /ay/ in Smith Island are given in Table 1. Raw figures are not given for Ocracoke, since they have been provided in our previous descriptions of Ocracoke /ay/ (Wolfram and Schilling-Estes 1995; Schilling-Estes 1996). VARBRUL results for Ocracoke and Smith Island are given in Table 2. Figure 2 provides a graphic display of the comparative diachronic patterning of /ay/ raising in prevoiceless and prevoiced environments.

Two noteworthy contrasts are evident from the comparison of Smith Island and Ocracoke /ay/ raising provided in Table 2 and Figure 2. First, is the direction of change. Instead of showing a decline for /ay/ raising/backing, as in Ocracoke, Smith Island shows a significant increase in raised /ay/. This increase hardly appears to be a temporary revitalization before an inevitable decline, as we have found with raised /ay/ for certain middle-aged men in Ocracoke (Wolfram and Schilling-Estes 1995). Instead, it appears to represent a robust change in progress, as evidenced by the steadily increasing usage levels for raised /ay/ among middle-aged and younger Smith Islanders.

Second is the differential ordering of phonological constraints affecting /ay/ raising in each community. Although the

Figure 2. The Patterning of Raised /ay/ over Time

The backed, raised variant is favored in prevoiced environments in Ocracoke, in Smith Island raising is favored in prevoiceless contexts and disfavored in the prevoiced environment, just as is /ay/ raising in Canadian English and a number of U.S. varieties (Labov 1963; Chambers 1973). The contrasting constraint orders may be explained by pointing to the fact that the Ocracoke variant is backed as well as raised, while the Smith Island raised variant seems relatively centralized. In other words, Ocracoke raised /ay/, phonetically more like [aʰ], is located in peripheral vowel space, while Smith Island raised /ay/, located in the phonetic space of [ɛ], could be considered nonperipheral. We have proposed (Wolfram and Schilling-Estes 1995) that peripheral and nonperipheral vowels may display mirror image constraint orderings in terms of the sonority hierarchy; thus, raised, backed [aʰ] is more frequent in prevoiced position in Ocracoke but raised and centralized [ɛ] is more frequent in the prevoiceless environment in varieties such as Smith Island English and Canadian English.

There is another way in which Smith Island differs from Ocracoke with respect to /ay/. We have noted that in Ocracoke, raised and backed [aʰ] is a symbolic icon and the object of countless comments by outsiders and islanders. It is also highlighted in performances of the dialect (Schilling-Estes 1995, 1996). In Smith Island, however, raised /ay/ goes virtually unnoticed, despite its dramatic increase in island speech. As we discuss below, the realization of /aw/ with a fronted glide displays the opposite patterning in terms of social salience in the two island communities: Fronted /aw/ serves as a stereotype in Smith Island, where everybody talks about it. In Ocracoke, /aw/ is a marker but not a stereotype, and few islanders comment on it in their discussions of island speech.

3. The Patterning of /aw/ in Ocracoke and Smith Island

Our incipient qualitative and quantitative analysis of /aw/ in Ocracoke and Smith Island addresses several issues central to the comparative investigation of dialect change in moribund dialects. We are obviously concerned with cross-dialectal comparison of
changes in /aw/ and /ay/ in Smith Island and Ocracoke. We are further concerned with how these two diphthongs compare with each other synchronically and diachronically as part of the diphthongal subsystem of English. And finally, we are interested in the consequences of the differential symbolic status ascribed to /aw/ and /ay/ in these two communities.

Thus far, we have extracted data on /aw/ for 10 speakers representing three generations of speakers from Smith Island and seven representative speakers from our Ocracoke sample. In our initial attempts to delimit possible variants of the nucleus and glide of /aw/, we posited that variants of the nucleus might be categorized along the raised-unraised or fronted-unfronted dimensions and that glides might be categorized as fronted, non-fronted, or absent (when /aw/ is realized as a monophthong). Given that the fronting of the glide of /aw/ is considered to be contingent upon the fronting of the nucleus which pulls the glide along with it (Labov, Yaeager and Steiner 1972), we might expect that variants of the /aw/ nucleus would always accompany a fronted glide. However, preliminary spectrographic analysis has led us to call this assumption into question. We are even questioning the categorization of variants of the nucleus in terms of binary classifications such as raised/unraised, and fronted/non-fronted, as well as the salience of these distinctions for islanders, since no clear patterns in terms of the /aw/ nucleus with respect to these either of these two dimensions have yet emerged in our spectrographic analysis. However, the distinction between fronted and non-fronted glides seems relatively clear.

In Figure 3, partial vowel charts based on our spectrographic analysis are given for two speakers from Ocracoke; and in Figure 4, partial vowel charts are given for two speakers from Smith Island. The two Ocracoke speakers are a 39-year-old male and and 18-year-old male; the two Smith Islanders are a 41-year-old female and a 15-year-old female. Points represent mean F1 and F2 values for several tokens of each vowel. Measurements are given for several different types of phonetic environments, including prevoiceless (e.g. house, out), prenasal (e.g. down, brown) and word-final (e.g. how, now). Other vowels (e.g. /i/, /e/, /æ/, and /a/) are given as anchor points for situating the production of /aw/. 

Figure 3. The Positioning of /aw/ and /ay/ in Ocracoke

a. RO, 39-year-old male

b. BB, 18-year-old male
The spectrographic analysis for the 39-year-old Ocracoker whose vowel chart is given in Figure 3a reveals fronting of the /aw/ nucleus and glide in prevoiceless and prenasal position. Incidentally, this speaker also happens to be one of the middle-aged men in our Ocracoke sample who shows high usage levels for raised /ay/; in fact, he is Rex O'Neal, the speaker whose exaggerated /ay/ raising is highlighted in Schilling-Estes' (1995, 1996) discussions of "performance" speech. Although we might maintain that Rex's fronting of the /aw/ nucleus is simply a reflection of his generalized fronting of back vowels, as indicated by a complete spectrographic analysis of his vowel system by Erik Thomas, the fact that the /aw/ glide in word-final position is quite far back causes us to question this assumption. The back-gliding of word-final /aw/ is categorical for all speakers in Ocracoke and Smith Island that we have so far examined, even those with extensive front gliding of /aw/ in other environments. This suggests that /aw/ has undergone an allophonic split.

The 18-year-old Ocracoke speaker whose vowels are plotted in Figure 3b shows a fairly typical pattern for a younger speaker with respect to /aw/ gliding in Ocracoke. The trajectory of his glide is backward regardless of the following phonetic environment, except in prenasal position, where /aw/ is sometimes unglided. Interestingly, this speaker is atypical of younger islanders in terms of /ay/ raising. Despite his lack of the distinctive island /aw/ variant, he is one of the few younger speakers in our sample who shows significant usage levels for the distinctive /ay/ variant (about 40 percent). We hypothesize that this selective pattern of retention—keeping the traditional Ocracoke [a̯^21] but losing the distinctive /aw/—is one manifestation of the differential symbolic status ascribed to /ay/ and /aw/ in Ocracoke. Those seeking to project their status as islanders through language may preserve raised, backed /ay/, while glide-fronted /aw/ readily gives way to the mainland back-gilded variant [a̯^2].

The positioning of the nucleus and glide of /ay/ for Smith Islanders is indicated in the representative vowel charts in Figure 4. The first speaker, a 41-year-old female, indicates some nucleus fronting, particularly in the prenasal environment, but not much raising of the nucleus. The fronted trajectory of her glide, however, is clearly evident, even in environments where a fronted
nucleus is not evident, for example, in prevoiceless position. Thus, it appears that glide fronting may not be phonetically contingent upon nucleus fronting, as suggested, for example, in Labov, Yaeger, and Steiner (1972). Another possible explanation for this apparent incongruence is that the social marking of /aw/ in Smith Island has led speakers to seize on a phonetically unnatural variant, because such a variant may be more noticeable than a phonetically expected one.

There are two cases in which JK, the speaker in Figure 4a, does not produce clearly fronted glides. First, the /aw/ glide shows a backward trajectory in word-final position, as it did for the Ocracoke speakers represented in Figure 3. Second, /aw/ is back-glided in prevoiceless and prenasal environments when JK demonstrates /aw/ vowels that are different from her own—for example, those of her mother. The positioning of the nucleus and glide of these tokens relative to JK’s ordinary conversational tokens is given in Figure 5.

Figure 5. Demonstrating Smith Island and Mainland /aw/

The role of /aw/ in linguistic demonstration is indicative of its salience in Smith Island, especially in contrast with the relatively non-salient /ay/ diphthong. For example, consider the following excerpt from JK’s sociolinguistic interview. In this passage, JK is discussing her mother’s lack of glide-fronting for /aw/ compared with her own use. The phonetic production of each case of /aw/ and /ay/ in the conversation is given in broad transcription. Glide-fronted /aw/ is represented as [as1]; nucleus-raised /ay/ would be represented as [a], if it had occurred in this passage.

(3) JK: Well, my mother was from Tylerton. I say, um, house [ha1's], brown [bra1'n], you know, just as flat and broad as it can be. But they—she still says house [ha1's] and brown [bra1'n].

FW: Just like—like I would.

JK: Yeah, mmhmm. They say it down [da1'n] there ... down [da1'n], down [da1'n]. I don’t know if she says—I don’t know about down [da1'n]. I know about house [ha1's]. I know about that.

FW: Now she would say, just like this: Would she say house [ha1's]?

JK: Uhhuh. Yep. And I say house [ha1's]. I heard her say house [ha1's], but I say house [ha1's]. Cause that’s how Tylerton says that. I can pick up a—I don’t know how to say it, up at Rhodes Point, it seems like they say—use the long uh /ay/ [a]. Like I say pie [pa1]. And maybe that’s right, but it’s like they go pie [pa1']. It’s like a long /ay/ or something in there. I can just pick it up. I don’t even know if I’m saying...

FW: You can’t necessarily copy it, but you can hear it.

JK: No, no, I can’t say it.

The conversation shows that JK is quite proficient in producing different variants of /aw/, including the glide-fronted variant that typifies Smith Island speech. However, she fails in her attempts to produce different /ay/ variants, even though she insists that she can hear them. Most likely, her ability to demonstrate
variants of /aw/ but not /ay/ is indicative of a greater awareness of /aw/ and its variant realizations. The conversation also indicates that JK is aware that glide-fronted /aw/ is more prevalent in the speech of middle-aged islanders such as herself than older islanders such as her mother.

The younger Smith Islander, DE, whose partial vowel chart is given in Figure 4b, shows a pattern similar to the middle-aged speaker in terms of her /aw/ production; she indicates generalized glide-fronting for /aw/, except in word-final position. Her nucleus appears more raised than the middle-aged speaker’s, yet it is not clearly fronted. At this point, we are uncertain whether to categorize the raising of the /aw/ nucleus in Smith Island as a fronted and raised variant which is part of the Southern Vowel Shift or as a centralized raised variant which represents a retrograde movement, as in Martha’s Vineyard English (1963) or Canadian English (Chambers 1973). We are not even sure that such a categorization is relevant to the social marking of /aw/, since it appears to be the trajectory of the glide rather than the position of the nucleus which makes Smith Island /aw/ so noticeable to islanders and outsiders.

Like the middle-aged Smith Islander, the 15-year-old islander produces a backed glide for /aw/ in demonstrating mainland /aw/ variants, while the front-glided variant is prevalent in other contexts. In fact, her glide fronting is so prevalent that it sometimes leads to real-life cross-dialectal misinterpretation. Consider, for example, DE’s report of confusion concerning /aw/ that took place in the mainland town of Salisbury, Maryland. The conversation in (4) takes place between the fieldworker (FW) and two Smith Islanders (LAE and DE) who were 13 and 15, respectively, at the time of the interview.

(4) LAE: We say down [da'n] and south [sæ't] and all that; we don’t say it the way you talk—I don’t know how to say it.
FW: Down [da'n] and sound [sa'nd].
LAE: Yeah, like that.
DE: One time I was in the Salisbury Mall, and I had this brown [bra'n] pocketbook. And I went in the shoe store, and I left it in there, and I went in there and told that man, I said, “Have you seen a brown [bra'n] pocketbook in here?” He couldn’t understand me, how I said it. And he went back there and got—he understood ‘pocketbook’. He went back there and he said, “Is this yours?” I said, “Yeah.”
FW: Did you point to it and say, “See? See what color it is?”
DE: Yeah. I tried to talk—I said brown [bra'n]. I couldn’t say it good; he still couldn’t understand me.

The young speakers in this interview, like the 41-year-old speaker cited above, manipulates the glide-fronted and non-glide-fronted variants of /aw/ fairly readily, indicating greater awareness of /ay/ variants than those of /ay/. There are a number of discussions of /aw/ like this one and the one in (3) in the Smith Island interviews, as well as observations by outsiders about this feature. By contrast, there is relatively little overt discussion of /ay/, and islanders do not seem to be able to demonstrate the raised variant [ɔː] which is becoming more and more prevalent in their speech. In other words, these speakers are not able to demonstrate their awareness of the [ɔː] variant either through direct comment or through what Preston (1996) refers to as “definition by ostentation.”

Conversely, Ocracokers are quick to demonstrate what it is that is unique about their /ay/ vowel while ignoring /aw/. For example, Rex O’Neal, the speaker of the Ocracoke dialect studied in Schilling-Estes’ examination of performance speech (1995, 1996) indicates greater height for the nucleus of /ay/ in speech performances than in non-performance speech. Although his stock performance phrase, *It’s high tide on the sound side*, also contains an /aw/ vowel in addition to three /ay/’s, spectrographic measurements reveal that he is not able to seize on the feature of /aw/ glide-fronting in his speech performances. In fact, his performance production of /aw/ is actually less glide-fronted than his production of /aw/ in ordinary conversation during his sociolinguistic interview. Measurements for /aw/ in Rex’s performance and non-performance speech are given in Figure 6.
A preliminary quantitative analysis of glide-fronted /aw/ based on 10 Smith Island and seven Ocracoke speakers reveals a contrast between Ocracoke and Smith Island as dramatic as that indicated by our quantitative analysis of /ay/. In Tables 3 and 4, we present raw figures and VARBRUL analysis results for /aw/ glide-fronting in the two communities. A graphic comparison is given in Figure 7. The internal factor group is following environment, which is limited to prevoiceless and prenasal environments because there are very few examples of prevoiced /aw/.

The results of our preliminary quantitative analysis indicate that glide-fronted /aw/ is increasing dramatically on Smith Island, particularly between old and middle-aged speakers but also between middle-aged and younger speakers. Thus, the move toward /aw/-fronting appears to represent a robust, rapid language change in progress.

Conversely, there has been a rapid decline in glide-fronted /aw/ on Ocracoke. At this point, we are not quite sure what to make of the fact that middle-aged Ocracokers display a higher incidence of glide-fronted /aw/ than older speakers. One possibility is that a change in progress toward increased fronting was abandoned in the face of competition from mainland /aw/. In light of the small sample of speakers and the high Chi-square per cell scores (3.149) indicated in our VARBRUL analysis, we are hesitant to draw any definite conclusions at this point. What is clear from our analysis thus far, however, is that glide-fronted /aw/ is drastically receding without fanfare in Ocracoke while it is rapidly expanding in Smith Island—with considerable fanfare.

Table 4. VARBRUL Results for /aw/ glide-fronting

VARBRUL Results: Ocracoke

Application = glide fronting
Input Probability = .07

Age Group:
Older = .62
Middle-aged = .75
Young = .19

Sex:
Female = .36
Male = .65

Following Environment:
Voiceless Obstruent = .46
Nasal = .56
Chi-square per cell = 3.149

VARBRUL Results: Smith Island

Application = glide fronting
Input Probability = .30

Age Group:
Older = .02
Middle-aged = .74
Young = .84

Sex:
Female = .76
Male = .24

Following Environment:
Voiceless Obstruent = .44
Nasal = .61
Chi-square per cell = 1.359

4. Conclusion

The examination of /ay/ and /aw/ in Ocracoke English and Smith Island English has shown that cross-dialectal variants that appear, at first glance, to be somewhat similar may turn out to be quite different in terms of (1) their status within their respective vowel system configurations, (2) the directionality of the linguistic change affecting the variants, and (3) the social embedding and evaluation of the linguistic changes taking place. With respect to the status of /ay/ and /aw/ within the Ocracoke and Smith Island vowel systems, we see differences in peripherality, at least for /ay/. Raised /ay/ in Ocracoke is located in peripheral vowel space, while Smith Island raised /ay/ is non-peripheral. This differential status with respect to peripherality most likely explains the differential ordering of constraints affecting /ay/ raising in the two varieties.

We were also struck by the fact that, whereas Ocracoke /ay/ nucleus-raising and /aw/ glide-fronting appear to be part of the expected continuation of the Southern Vowel Shift, Smith Island /ay/ raising seems to be a retrograde movement, just like Canadian Raising and Martha's Vineyard raising. It may be that varieties undergoing death by concentration are more prone to initiate retrograde movements than those undergoing death by dissipation—perhaps as a defense against the outside language variants that win out in communities like Ocracoke.

The differential social marking of /ay/ and /aw/ in Ocracoke and Smith Island also seems to have an effect on the progression of change. The recession of /ay/ backing/raising in Ocracoke has been shown to be somewhat irregular, both in terms of its change slope and its phonetic conditioning. Meanwhile, the more socially unobtrusive marker /aw/ seems to be receding in a regular way. On Smith Island, raised /ay/ is increasing steadily and straightforwardly, in a phonetically natural manner. However, the more obtrusive /aw/ shows no clear pattern in the directionality of the movement of its nucleus; and it appears that the glide may be fronted independently of the nucleus—a phenomenon which is quite unexpected, phonetically. We suggest further that there will be a difference in the stylistic manipulation of changing dialect features based on their symbolic role and their level of consciousness. Ocracokers indicate "definition by ostentation" for /ay/ but
Symbolic Identity

not for /aw/, while Smith Islanders apparently show the converse. Thus, the symbolic meaning of dialect features has important implications for stylistic manipulation in dialect change and death.

Our examination of /aw/ and /ay/ demonstrates that the dissipation model of dialect death is not applicable to all endangered dialect situations. Dialect recession in Smith Island seems to be characterized by CONCENTRATION or INTENSIFICATION, in which the dialect actually gains in strength as it loses speakers, leading to a sort of ‘survival of the dialect fittest.’ We are impressed with how rapidly raised /ay/ and glide-fronted /aw/ in Ocracoke are fading; for Smith Island, we are impressed with how fast the changes toward glide-fronted /aw/ and raised /ay/ are progressing. Dialect endangerment due to the loss of speakers rather than extended contact with speakers of other dialects may lead to the compressed intensification of structures, just as linguistic swamping may lead to a rapid loss of features.

Before we confronted the case of dialect intensification in Smith Island, we were not aware that post-insular dialects could become so distinctive as they moved towards death. We were not alone in this belief. Despite the apparent awareness of Smith Islanders that glide-fronted /aw/ is expanding in their community, as evidenced in the excerpt in (3), other comments from interviews suggest that Smith Islanders firmly believe that their dialect is becoming diluted as it dies. Sometimes, however, contrary to popular opinion and scholarly belief, the more things seem the same, the more they may actually differ.
