Parametric Pseudo-Manifolds

Abstract
We introduce a novel and constructive definition of gluing data, and prove that a universal manifold can always be constructed from any set of gluing data. We also present a class of spaces called parametric pseudo-manifolds, which under certain conditions are manifolds embedded in $\mathbb{R}^n$ and defined from sets of gluing data. The combination of both definitions is equivalent to a constructive definition of manifolds. They also enable us to develop constructions that explicitly yield manifolds in $\mathbb{R}^n$ arising in several graphics and engineering applications.

Abstract

We introduce a novel and constructive definition of gluing data, and prove that a universal manifold can always be constructed from any set of gluing data. We also present a class of spaces called parametric pseudo-manifolds, which under certain conditions are manifolds embedded in \( \mathbb{R}^n \) and defined from sets of gluing data. The combination of both definitions is equivalent to a constructive definition of manifolds. They also enable us to develop constructions that explicitly yield manifolds in \( \mathbb{R}^n \) arising in several graphics and engineering applications.
1 Introduction

Some graphics, engineering, and artificial intelligence applications, including surface modeling [1], rendering and simulation on surfaces [2, 3, 4, 5], spherical imagery [6, 7], and manifold learning [8], deal with abstract objects that can be naturally defined as differentiable manifolds embedded in $\mathbb{R}^n$. In most cases, these objects are surfaces in $\mathbb{R}^3$ with arbitrarily large genus, but they can also be image panoramas [9], the space of bi-directional reflectance distribution functions (BRDF’s) [10], or more general manifolds embedded in $\mathbb{R}^n$ and generated by techniques of dimensionality reduction [11].

A common feature of all applications mentioned above is that they all need to build a manifold. For this purpose, the modern notion of manifold, which has been known and studied by mathematicians since the early 1900’s, is not very helpful. The reason is that this notion (see Definition 2.5) is not constructive, in the sense that it does not tell us how to build a manifold. The lack of a constructive definition led many researchers and practitioners to representing manifolds by less powerful mathematical objects, making it difficult or even impossible to do differential calculus on them.

In 1995, Cindy Grimm and John Hughes [12] gave the first constructive definition of a manifold. They also provided an approach, based on their constructive definition, for building surfaces in $\mathbb{R}^3$ that approximate polygonal meshes, a classic problem in surface modeling [1]. Their approach explicitly builds an atlas for the surface by “gluing” open sets in $\mathbb{R}^2$, and by defining functions, i.e., parametrizations, that take these open sets onto the surface in $\mathbb{R}^3$. The idea of gluing open sets to build manifolds is not new. André Weil introduced this idea to define abstract algebraic varieties by gluing irreducible affine sets in his book [13] published in 1946 (Chapter VII, Section 3, page 179). However, as far as we know, Grimm and Hughes [12] were the first to come up with a practical approach.

The surfaces built by the manifold-based construction in [12] are $C^2$. But, it was clear since then that $C^k$ surfaces, for $k > 2$ or even $k = \infty$, could be more easily created by the approach in [12] than by all previously developed surface constructions. Furthermore, the existence of an atlas for the surface allows for a more natural and elegant way of solving differential equations on surfaces, such as the ones in [2, 4, 5]. The pioneering work of Grimm and Hughes caught the attention of several researchers in the field of surface modeling, and more powerful, manifold-based constructions for surfaces were developed [12, 14, 15, 16, 17, 18]. Most of these constructions are based on the
theoretical framework developed by Grimm and Hughes. Their work also inspired the development of manifold-based techniques for surface manipulation, such as the remeshing algorithm described in [19].

Here, we introduce a new constructive definition of manifold. In particular, we formally define gluing data, and prove that a “universal” manifold can always be constructed from a set of gluing data through a (constructive) gluing process. Our definition improves upon the one given by Grimm and Hughes in [12]. The main differences are two-fold. First, our definition fixes a problem with their definition. Second, we give a necessary and sufficient condition for the manifold to be Hausdorff. The condition given in [12] is only sufficient, and it excludes some Hausdorff manifolds from being constructed. We also introduce the notion of parametric pseudo-manifolds (PPM’s for short), which under certain conditions are manifolds embedded in $\mathbb{R}^n$. We believe that PPM’s are powerful representations for the manifolds arising in applications such as the ones described in [1, 2, 3, 4, 5, 6, 7, 9].

Defining explicit gluing data from a simplicial surface, especially the transition functions $(\varphi_{ji})$, is harder than it appears at first glance. The main difficulty is to find smooth diffeomorphisms which satisfy the cocycle condition (condition 3c of Definition 3.1). We provide an original solution involving domains which are the interior of disks and simple functions which are linear in polar coordinates (see Section 5).

The remainder of this paper is organized as follows. Section 2 recalls the basic notions of charts, atlases, and manifolds. Section 3 introduces our definition of sets of gluing data, and also presents our proof that a universal manifold can always be built from such a set. Section 4 gives the definition of parametric pseudo-manifolds, and discusses some of their properties. Section 5 describes a constructive process for building sets of gluing data from simplicial surfaces. This kind of gluing data has been used in the construction of $C^\infty$-surfaces that approximate simplicial surfaces (we refer the interested reader to [18]), and it shows the applicability of our constructive definitions of gluing data and PPM. Section 6 presents our concluding remarks and some open problems, and discusses future work. Appendix A presents a proof for the correctness of the construction described in Section 5.
2 Charts, atlases, and manifolds

This section reviews standard notions related to the topic of this paper. Our presentation is based on many sources, including Warner [20], Berger and Gostiaux [21], O’Neill [22], do Carmo [23, 24], and Tu [25].

Given $\mathbb{R}^n$, recall that the projection functions, $pr_i : \mathbb{R}^n \to \mathbb{R}$, for all $i \in \{1, \ldots, n\}$, are defined by

$$pr_i(x_1, \ldots, x_n) = x_i.$$

**Definition 2.1.** Given a topological space, $M$, a chart (or local coordinate function) is a pair, $(U, \varphi)$, where $U$ is an open subset of $M$ and $\varphi : U \to \Omega$ is a homeomorphism onto an open subset, $\Omega = \varphi(U)$, of $\mathbb{R}^{n_\varphi}$ (for some $n_\varphi \geq 1$). For any $p \in M$, a chart, $(U, \varphi)$, is a chart at $p$ iff $p \in U$. If $(U, \varphi)$ is a chart, then the functions $x_i = pr_i \circ \varphi$ are called local coordinates and for every $p \in U$, the tuple $(x_1(p), \ldots, x_n(p))$ is the set of coordinates of $p$ with respect to the chart. Finally, the “inverse” chart, $(\Omega, \varphi^{-1})$, is called a local parametrization.

**Definition 2.2.** Given any two charts, $(U_i, \varphi_i)$ and $(U_j, \varphi_j)$, on a topological space, $M$, if $U_i \cap U_j \neq \emptyset$, we define the transition maps, $\varphi_{ji} : \varphi_i(U_i \cap U_j) \to \varphi_j(U_i \cap U_j)$ and $\varphi_{ij} : \varphi_j(U_i \cap U_j) \to \varphi_i(U_i \cap U_j)$, as

$$\varphi_{ji} = \varphi_j \circ \varphi_i^{-1} \quad \text{and} \quad \varphi_{ij} = \varphi_i \circ \varphi_j^{-1}.$$

Figure 2.1 illustrates Definition 2.2.

Clearly, we have $\varphi_{ij} = \varphi_{ji}^{-1}$. We also have that $\varphi_{ij}$ and $\varphi_{ji}$ are maps between open sets of $\mathbb{R}^n$.

**Definition 2.3.** Given a topological space, $M$, given an integer $n \geq 1$, and given some $k$ such that $k$ is either a positive integer or $k = \infty$, a $C^k$ n-atlas (or n-atlas of class $C^k$), $\mathcal{A}$, on $M$ is a family of charts, $\{(U_i, \varphi_i)\}_I$, where $I$ is a nonempty (and possibly uncountable) index set, such that the following holds:

---

1In practice, the set $I$ is countable and even finite.
(1) \( \varphi_i(U_i) \subseteq \mathbb{R}^n \), for all \( i \);

(2) the family \( \{U_i\}_{i \in I} \) is an open cover for \( M \), i.e.,

\[
M = \bigcup_{i \in I} U_i;
\]

and

(3) whenever \( U_i \cap U_j \neq \emptyset \), the transition map \( \varphi_{ji} \) (resp. \( \varphi_{ij} \)) is a \( C^k \) diffeomorphism (when \( k = \infty \), the \( \varphi_{ji} \) are smooth diffeomorphisms).

![Figure 2.1: Illustration of the definition of transition maps.](image)

The existence of a \( C^k \) \( n \)-atlas on a topological space, \( M \), is sufficient to establish that \( M \) is an \( n \)-dimensional \( C^k \) manifold, but there is still a minor subtlety in the actual definition of a manifold. This has to do with the fact that there may be many choices of atlases, but it is useful to think of a manifold as an object independent of the choice of atlas. To do so, we define the notion of atlas compatibility.

**Definition 2.4.** Given a \( C^k \) \( n \)-atlas, \( \mathcal{A} \), on \( M \), for any other chart, \( (U, \varphi) \), we say that \( (U, \varphi) \) is compatible with the atlas \( \mathcal{A} \) iff every map \( \varphi_i \circ \varphi^{-1} \) and \( \varphi \circ \varphi_i^{-1} \) is \( C^k \) (whenever \( U \cap U_i \neq \emptyset \)). Two atlases, \( \mathcal{A} \) and \( \mathcal{A}' \), on \( M \) are said to be compatible iff every chart of one is compatible with the other atlas.
To say that two atlases are compatible is equivalent to saying that the union of the two atlases is still an atlas. Atlas compatibility induces an equivalence relation on $C^k$-atlases on $M$. In particular, given an atlas, $\mathcal{A}$, for $M$, the collection, $\tilde{\mathcal{A}}$, of all charts compatible with $\mathcal{A}$ is a maximal atlas in the equivalence class of charts compatible with $\mathcal{A}$. Finally, we have the definition of a manifold:

**Definition 2.5.** Given an integer $n \geq 1$ and given some $k$ such that $k$ is either a positive integer or $k = \infty$, a $C^k$ manifold of dimension $n$ consists of a topological space, $M$, together with an equivalence class, $\mathcal{A}$, of $C^k$-atlases on $M$. Any atlas, $A$, of $\mathcal{A}$ is called a differentiable structure of class $C^k$ (and dimension $n$) on $M$. When $k = \infty$, we say that $M$ is a smooth manifold of dimension $n$.

For technical reasons (in particular, to ensure the existence of partitions of unity) and to avoid “esoteric” manifolds that do not arise in the practical applications we mention in this paper, from now on, all topological spaces under consideration will be assumed to be Hausdorff and second-countable.

We can allow $k = 0$ in the above definitions. If this is the case, then condition 3 of Definition 2.3 is void, since a $C^0$ diffeomorphism is just a homeomorphism, but $\varphi_{ji}$ is always a homeomorphism. When $k = 0$ we call $M$ a topological manifold of dimension $n$. We do not require a manifold to be connected but we require all components to have the same dimension, $n$. Actually, on every connected component of $M$, it can be shown that the dimension, $n_{\varphi}$, of the range of every chart is the same. This is quite easy to show if $k \geq 1$ but for $k = 0$, this requires a deep theorem of Brouwer (the Invariance of Domain Theorem). We can also allow $n = 0$ in the above definitions. If this is the case, then every one-point subset of $M$ is open. So, every subset of $M$ is open, i.e., $M$ is any countable set (as we assumed $M$ to be second-countable) with the discrete topology. Finally, note that every manifold is locally compact and locally connected, as $\mathbb{R}^n$ is locally compact and locally connected.

For an example of a manifold, consider the sphere $S^n \subset \mathbb{R}^{n+1}$,

$$S^n = \{(x_1, \ldots, x_{n+1}) \in \mathbb{R}^{n+1} \mid \sum_{i=1}^{n+1} x_i^2 = 1\}.$$

We can regard $S^n$ as a topological space by giving $S^n$ the topology consisting of all subsets $U$ of $S^n$ such that, for every $p = (p_1, \ldots, p_{n+1}) \in U$, there exists a real number $\delta$, with $\delta > 0$, such
that \((S^n \cap B_\delta(p, \mathbb{R}^{n+1})) \subseteq U\), where \(B_\delta(p, \mathbb{R}^{n+1})\) is the open ball in \(\mathbb{R}^{n+1}\) of center \(p\) and radius \(\delta\). Using the stereographic projection, we can define two charts on \(S^n\). In fact, denote the points \((0, \ldots, 0, 1) \in \mathbb{R}^{n+1}\) and \((0, \ldots, 0, -1) \in \mathbb{R}^{n+1}\) by \(N\) (the north pole) and \(S\) (the south pole), respectively, and let

\[
\varphi_N: S^n \setminus \{N\} \to \mathbb{R}^n \quad \text{and} \quad \varphi_S: S^n \setminus \{S\} \to \mathbb{R}^n
\]

be given by

\[
\varphi_N(x_1, \ldots, x_{n+1}) = \frac{1}{1-x_{n+1}}(x_1, \ldots, x_n) \quad \text{and} \quad \varphi_S(x_1, \ldots, x_{n+1}) = \frac{1}{1+x_{n+1}}(x_1, \ldots, x_n),
\]

which are called stereographic projection from the north pole and stereographic projection from the south pole, respectively.

The inverse stereographic projections are given by

\[
\varphi_N^{-1}(x_1, \ldots, x_n) = \frac{1}{\left(\sum_{i=1}^n x_i^2\right)} + 1 \left(2x_1, \ldots, 2x_n, \left(\sum_{i=1}^n x_i^2\right) - 1\right)
\]

and

\[
\varphi_S^{-1}(x_1, \ldots, x_n) = \frac{1}{\left(\sum_{i=1}^n x_i^2\right)} + 1 \left(2x_1, \ldots, 2x_n, -\left(\sum_{i=1}^n x_i^2\right) + 1\right).
\]

Note that \(\varphi_N\) and \(\varphi_S\) are homeomorphisms that map open sets of \(S^n\) to open sets of \(\mathbb{R}^n\) (regarding \(\mathbb{R}^n\) as a topological space equipped with the usual topology). So, \((U_N, \varphi_N)\) and \((U_S, \varphi_S)\) are charts. Furthermore, if we let \(U_N = S^n \setminus \{N\}\) and \(U_S = S^n \setminus \{S\}\), we see that (1) \(\varphi_N(U_N) = \mathbb{R}^n\) and \(\varphi_S(U_S) = \mathbb{R}^n\), (2) \(\{U_N, U_S\}\) is an open cover for \(S^n\), and (3) it is easily checked that on the overlap,

\[
U_N \cap U_S = S^n \setminus \{N, S\},
\]

the transition maps,

\[
\varphi_{SN} = \varphi_S \circ \varphi_N^{-1} \quad \text{and} \quad \varphi_{NS} = \varphi_N \circ \varphi_S^{-1}
\]

are given by

\[(x_1, \ldots, x_n) \mapsto \frac{1}{\sum_{i=1}^n x_i^2}(x_1, \ldots, x_n),\]

which is a smooth bijection on \(\mathbb{R}^n \setminus \{O\}\). So, \((U_N, \varphi_N)\) and \((U_S, \varphi_S)\) form a smooth \(n\)-atlas on \(S^n\).

Now, let us consider the curve \(C \subset \mathbb{R}^2\) given by the zero locus of equation \(y^2 = x^2 - x^3\) (i.e., a nodal cubic):

\[
C = \{(x, y) \in \mathbb{R}^2 \mid y^2 = x^2 - x^3\}.
\]
This curve is not a manifold. The reason is that the curve has a self-intersection at the origin (see Figure 2.2). If \( C \) were a manifold, then there would be a connected open subset, \( U \subset C \), containing the origin \( O = (0,0) \), namely the intersection of a small enough open disc centered at \( O \) with \( C \), and a local chart, \( (U, \varphi) \), with \( \varphi: U \to \Omega \), where \( \Omega \) is some connected open subset of \( \mathbb{R} \) (that is, an open interval), since \( \varphi \) is a homeomorphism. However, \( U - \{O\} \) consists of four disconnected components and \( \Omega - \varphi(O) \) of two disconnected components, contradicting the fact that \( \varphi \) is a homeomorphism.

Figure 2.2: A nodal cubic is not a manifold.

3 Sets of gluing data for manifolds

The definition of a manifold (see Definition 2.5) assumes that the topological space, \( M \), is already known. However, there are situations of practical interest in which we only have some indirect information about the overlap of the domains, \( U_i \), of the local charts in terms of the transition maps,

\[
\varphi_{ji} : \varphi_i(U_i \cap U_j) \to \varphi_j(U_i \cap U_j),
\]

but where the manifold \( M \) itself is not known. This is the case when trying to build a smooth surface to approximate a mesh in \( \mathbb{R}^3 \) [12, 14, 15, 16, 17, 18]. If we let \( \Omega_{ij} = \varphi_i(U_i \cap U_j) \) and \( \Omega_{ji} = \varphi_j(U_i \cap U_j) \), then

\[
\varphi_{ji} : \Omega_{ij} \to \Omega_{ji}
\]

can be viewed as a “gluing map” between two open subsets, \( \Omega_{ij} \) and \( \Omega_{ji} \), of \( \Omega_i \) and \( \Omega_j \), respectively. Remarkably, manifolds can be constructed from what we often call “gluing data” using the “gluing process” alluded to above. It is important to note that if the \( \Omega_{ij} \) arise from the charts of a manifold, then nonempty triple intersections \( U_i \cap U_j \cap U_k \) of domains of charts have images \( \varphi_i(U_i \cap U_j \cap U_k) \).
in $\Omega_i$, $\varphi_j(U_i \cap U_j \cap U_k)$ in $\Omega_j$, and $\varphi_k(U_i \cap U_j \cap U_k)$ in $\Omega_k$, and since the $\varphi_i$s are bijective,

$$\varphi_i(U_i \cap U_j \cap U_k) = \varphi_i(U_i \cap U_j \cap U_i \cap U_k) = \varphi_i(U_i \cap U_j) \cap \varphi_i(U_i \cap U_k) = \Omega_{ij} \cap \Omega_{ik},$$

and similarly

$$\varphi_j(U_i \cap U_j \cap U_k) = \Omega_{ji} \cap \Omega_{jk},$$
$$\varphi_k(U_i \cap U_j \cap U_k) = \Omega_{ki} \cap \Omega_{kj},$$

and these sets are related. Indeed, we have

$$\varphi_{ji}(\Omega_{ij} \cap \Omega_{ik}) = \varphi_j \circ \varphi_i^{-1}(\varphi_i(U_i \cap U_j) \cap \varphi_i(U_i \cap U_k))$$
$$= \varphi_j(U_i \cap U_j \cap U_k)$$
$$= \Omega_{ji} \cap \Omega_{jk},$$

and similar equations relating the other “triple intersections.” In particular,

$$\varphi_{ij}(\Omega_{ji} \cap \Omega_{jk}) = \Omega_{ij} \cap \Omega_{ik},$$

which implies that

$$\varphi_{ji}^{-1}(\Omega_{ji} \cap \Omega_{jk}) = \varphi_{ij}(\Omega_{ji} \cap \Omega_{jk}) \subseteq \Omega_{ik}.$$ 

In this Section, we formalize the notion of gluing data, describe the gluing process, and prove the correctness of this process in details provided a few mild assumptions on the gluing data.

**Definition 3.1.** Let $n$ be an integer with $n \geq 1$ and let $k$ be either an integer with $k \geq 1$ or $k = \infty$. A set of gluing data is a triple,

$$G = \left( (\Omega_i)_{i \in I}, (\Omega_{ij})_{(i,j) \in I \times I}, (\varphi_{ji})_{(i,j) \in K} \right),$$

satisfying the following properties, where $I$ and $K$ are (possibly infinite) countable sets, and $I$ is nonempty:

1. For every $i \in I$, the set $\Omega_i$ is a nonempty open subset of $\mathbb{R}^n$ called parametrization domain, for short, $p$-domain, and any two distinct $p$-domains are pairwise disjoint (i.e., $\Omega_i \cap \Omega_j = \emptyset$ for all $i \neq j$).
(2) For every pair \((i, j) \in I \times I\), the set \(\Omega_{ij}\) is an open subset of \(\Omega_i\). Furthermore, \(\Omega_{ii} = \Omega_i\) and \(\Omega_{ji} \neq \emptyset\) if and only if \(\Omega_{ij} \neq \emptyset\). Each nonempty subset \(\Omega_{ij}\) (with \(i \neq j\)) is called a *gluing domain*.

(3) If we let
\[
K = \{(i, j) \in I \times I \mid \Omega_{ij} \neq \emptyset\},
\]
then \(\varphi_{ji} : \Omega_{ij} \to \Omega_{ji}\) is a \(C^k\) bijection for every \((i, j) \in K\) called a transition (or gluing) map and such that

(a) \(\varphi_{ii} = \text{id}_{\Omega_i}\), for all \(i \in I\),

(b) \(\varphi_{ij} = \varphi^{-1}_{ji}\), for all \((i, j) \in K\), and

(c) For all \(i, j, k\), if \(\Omega_{ji} \cap \Omega_{jk} \neq \emptyset\), then \(\varphi_{ij}(\Omega_{ji} \cap \Omega_{jk}) = \Omega_{ij} \cap \Omega_{ik}\), and \(\varphi_{ki}(x) = \varphi_{kj} \circ \varphi_{ji}(x)\), for all \(x \in \Omega_{ij} \cap \Omega_{ik}\).

(4) For every pair \((i, j) \in K\), with \(i \neq j\), for every \(x \in \partial(\Omega_{ij}) \cap \Omega_i\) and \(y \in \partial(\Omega_{ji}) \cap \Omega_j\), there are open balls, \(V_x\) and \(V_y\), centered at \(x\) and \(y\), so that no point of \(V_y \cap \Omega_{ji}\) is the image of any point of \(V_x \cap \Omega_{ij}\) by \(\varphi_{ji}\).

There are several subtle points related to conditions 1–4 of Definition 3.1. First, we note that the index set \(I\) is assumed to be countable, which is consistent with the requirements of practical applications. For technical reasons that will become clear later, we also assume in condition 1 that any two \(p\)-domains, \(\Omega_i\) and \(\Omega_j\), with \(i \neq j\), are disjoint. But, this can always be achieved for manifolds, as the map
\[
\beta : (x_1, \ldots, x_n) \mapsto \left( \frac{x_1}{\sqrt{1 + \sum_{i=1}^n x_i^2}}, \ldots, \frac{x_n}{\sqrt{1 + \sum_{i=1}^n x_i^2}} \right)
\]
is a smooth diffeomorphism from \(\mathbb{R}^n\) to the open unit ball \(B_1(0, \mathbb{R}^n)\) whose the inverse map is given by
\[
\beta^{-1} : (x_1, \ldots, x_n) \mapsto \left( \frac{x_1}{\sqrt{1 - \sum_{i=1}^n x_i^2}}, \ldots, \frac{x_n}{\sqrt{1 - \sum_{i=1}^n x_i^2}} \right).
\]
In addition, since manifolds are assumed to be second-countable, we can use compositions of \(\beta\) with suitable translations to ensure that the \(\Omega_i\)'s are mapped diffeomorphically to disjoint open subsets of \(\mathbb{R}^n\). In condition 3, we are only interested in the \(\Omega_{ij}\)'s that are nonempty, but empty \(\Omega_{ij}\)'s do arise in proofs and constructions and this is why we allow empty gluing domains in condition 2.
Also, observe that $\Omega_{ij} \subseteq \Omega_i$ and $\Omega_{ji} \subseteq \Omega_j$. If $i \neq j$, then $\Omega_i$ and $\Omega_j$ are disjoint, and so are $\Omega_{ij}$ and $\Omega_{ji}$.

Condition 3c is called the **cocycle condition**. This condition may seem overly complicated, but it is actually needed to guarantee the transitivity of the relation, $\sim$, defined in the proof of Theorem 3.1. The problem is that $\varphi_{kj} \circ \varphi_{ji}$ is partial function whose domain, $\varphi_{ji}^{-1}(\Omega_{ji} \cap \Omega_{jk})$, is not necessarily related to the domain, $\Omega_{ik}$, of $\varphi_{ki}$. To ensure transitivity of $\sim$, we must assert that whenever the composition $\varphi_{kj} \circ \varphi_{ji}$ has a nonempty domain, this domain is contained in the domain of $\varphi_{ki}$, and that $\varphi_{kj} \circ \varphi_{ji}$ and $\varphi_{ki}$ agree, as illustrated by Figure 3.1. Since the $\varphi_{ji}$'s are bijective, condition 3c implies 3a and 3b. To get 3a, set $i = j = k$. Then, 3b follows from 3a and 3c by letting $k = i$.

![Figure 3.1: The cocycle condition of Definition 3.1.](image)

Finally, condition 4 ensures that the space obtained by gluing the $p$-domains is Hausdorff. As we shall prove later on, condition 4 is both necessary and sufficient. Figure 3.2 illustrates condition 4.

The idea of defining gluing data for manifolds is not new. André Weil introduced this idea to define abstract algebraic varieties by gluing irreducible affine sets in his book [13] published in 1946 (Chapter VII, Section 3, page 179). The same idea is well-known in bundle theory and can be found in standard texts such as Steenrod [26]. The beauty of the idea is that it allows the reconstruction of a manifold without having prior knowledge of the topology of this manifold, but by gluing open subsets of $\mathbb{R}^n$ (the $\Omega_i$'s) according to prescribed gluing instructions (namely, glue $\Omega_i$ and $\Omega_j$ by identifying $\Omega_{ij}$ and $\Omega_{ji}$ using $\varphi_{ji}$).
The gluing process clearly separates the local structure of the manifold (given by the $\Omega_i$’s) from its global structure, which is specified by the gluing functions. Furthermore, this method ensures that the resulting manifold is $C^k$ (even for $k = \infty$) with no extra effort since the $\varphi_{ji}$’s are assumed to be $C^k$. As far as we are concerned, Grimm and Hughes [12, 27] were the first to have realized the power of the gluing process for practical applications, and also to propose a manifold-based approach for fitting smooth surfaces to meshes in $\mathbb{R}^3$. However, the cocycle condition from the definition of a set of gluing in [12, 27] is not strong enough to ensure transitivity of the relation $\sim$. In addition, Grimm [27] uses a condition stronger than our condition 4 to ensure that the resulting space is Hausdorff. We will come back to these issues later. A correct definition of set of gluing data, with a necessary and sufficient Hausdorff condition, is among the main contributions of this paper.

Let us now prove that a $C^k$ manifold can be defined from a set of gluing data in a natural way:

**Theorem 3.1.** For every set of gluing data,

$$\mathcal{G} = \left( (\Omega_i)_{i \in I}, (\Omega_{ij})_{(i,j) \in I \times I}, (\varphi_{ji})_{(i,j) \in K} \right),$$

there is an $n$-dimensional $C^k$ manifold, $M_\mathcal{G}$, whose transition maps are the $\varphi_{ji}$’s.

**Proof.** Define the binary relation, $\sim$, on the disjoint union, $\bigsqcup_{i \in I} \Omega_i$, of the open sets, $\Omega_i$, as follows: For all $x, y \in \bigsqcup_{i \in I} \Omega_i$,

$$x \sim y \quad \text{iff} \quad (\exists (i, j) \in K)(x \in \Omega_{ij}, y \in \Omega_{ji}, y = \varphi_{ji}(x)).$$

Note that if $x \sim y$ and $x \neq y$, then $i \neq j$, as $\varphi_{ii} = \text{id}$. But then, as $x \in \Omega_{ij} \subseteq \Omega_i$, $y \in \Omega_{ji} \subseteq \Omega_j$ and $\Omega_i \cap \Omega_j = \emptyset$ when $i \neq j$, if $x \sim y$ and $x, y \in \Omega_i$, then $x = y$. We claim that $\sim$ is an equivalence

![Figure 3.2: The Hausdorff condition (condition 4) of Definition 3.1.](image-url)
relation. This follows easily from the cocycle condition. Clearly, condition 3a of Definition 3.1 ensures reflexivity, while condition 3b ensures symmetry. To check transitivity, assume that \( x \sim y \) and \( y \sim z \). Then, there are some \( i, j, k \) such that (i) \( x \in \Omega_{ij} \), \( y \in \Omega_{ji} \cap \Omega_{jk} \), \( z \in \Omega_{kj} \), and (ii) \( y = \varphi_{ji}(x) \) and \( z = \varphi_{kj}(y) \). Consequently, \( \Omega_{ji} \cap \Omega_{jk} \neq \emptyset \) and \( x \in \varphi_{ji}^{-1}(\Omega_{ji} \cap \Omega_{jk}) \), so by 3c, we get \( \varphi_{ji}^{-1}(\Omega_{ji} \cap \Omega_{jk}) = \Omega_{ij} \cap \Omega_{ik} \subseteq \Omega_{ik} \). So, \( \varphi_{ki}(x) \) is defined and by 3c again, \( \varphi_{ki}(x) = \varphi_{kj} \circ \varphi_{ji}(x) = z \), i.e., \( x \sim z \), as desired.

Since \( \sim \) is an equivalence relation, let

\[
M_G = \left( \prod_{i \in I} \Omega_i \right) / \sim
\]

be the quotient set and let \( p: \prod_{i \in I} \Omega_i \to M_G \) be the quotient map, with \( p(x) = [x] \), where \([x]\) denotes the equivalence class of \( x \) (see Figure 3.3). Also, for every \( i \in I \), let \( \text{in}_i: \Omega_i \to \prod_{i \in I} \Omega_i \) be the natural injection and let

\[
\tau_i = p \circ \text{in}_i: \Omega_i \to M_G.
\]

Since we already noted that if \( x \sim y \) and \( x, y \in \Omega_i \), then \( x = y \), we can conclude that every \( \tau_i \) is injective. We give \( M_G \) the coarsest topology that makes the bijections, \( \tau_i: \Omega_i \to \tau_i(\Omega_i) \), into homeomorphisms. Then, if we let \( U_i = \tau_i(\Omega_i) \) and \( \varphi_i = \tau_i^{-1} \), it is immediately verified that the \((U_i, \varphi_i)\) are charts and that this collection of charts forms a \( C^k \) atlas for \( M_G \). As there are countably many charts, \( M_G \) is second-countable. To prove that the topology is Hausdorff, we first prove the following:

**Claim.** For all \((i, j) \in I \times I\), we have \( \tau_i(\Omega_i) \cap \tau_j(\Omega_j) \neq \emptyset \) iff \((i, j) \in K\) and if so,

\[
\tau_i(\Omega_i) \cap \tau_j(\Omega_j) = \tau_i(\Omega_{ij}) = \tau_j(\Omega_{ji}).
\]

Assume that \( \tau_i(\Omega_i) \cap \tau_j(\Omega_j) \neq \emptyset \) and let \([z] \in \tau_i(\Omega_i) \cap \tau_j(\Omega_j)\). Observe that \([z] \in \tau_i(\Omega_i) \cap \tau_i(\Omega_j)\) iff \( z \sim x \) and \( z \sim y \), for some \( x \in \Omega_i \) and some \( y \in \Omega_j \). Consequently, \( x \sim y \), which implies that \((i, j) \in K\), \( x \in \Omega_{ij} \) and \( y \in \Omega_{ji} \). We have \([z] \in \tau_i(\Omega_{ij})\) iff \( z \sim x \), for some \( x \in \Omega_{ij} \). Then, either \( i = j \) and \( z = x \) or \( i \neq j \) and \( z \in \Omega_{ji} \), which shows that \([z] \in \tau_j(\Omega_{ji})\) and so, \( \tau_i(\Omega_{ij}) \subseteq \tau_j(\Omega_{ji}) \). Since the same argument applies by interchanging \( i \) and \( j \), we have

\[
\tau_i(\Omega_{ij}) = \tau_j(\Omega_{ji}),
\]

for all \((i, j) \in K \). Since \( \Omega_{ij} \subseteq \Omega_i \), \( \Omega_{ji} \subseteq \Omega_j \), and \( \tau_i(\Omega_{ij}) = \tau_j(\Omega_{ji}) \), for all \((i, j) \in K\), we have

\[
\tau_i(\Omega_{ij}) = \tau_j(\Omega_{ji}) \subseteq \tau_i(\Omega_i) \cap \tau_j(\Omega_j),
\]
for all \((i, j) \in K\).

For the reverse inclusion, if \([z] \in \tau_i(\Omega_i) \cap \tau_j(\Omega_j)\), then we know that there is some \(x \in \Omega_{ij}\) and some \(y \in \Omega_{ji}\) such that \(z \sim x\) and \(z \sim y\), so \([z] = [x] \in \tau_i(\Omega_{ij})\) and \([z] = [y] \in \tau_j(\Omega_{ji})\), and then we get

\[
\tau_i(\Omega_i) \cap \tau_j(\Omega_j) \subseteq \tau_i(\Omega_{ij}) = \tau_j(\Omega_{ji}).
\]

This proves that if \(\tau_i(\Omega_i) \cap \tau_j(\Omega_j) \neq \emptyset\), then \((i, j) \in K\) and

\[
\tau_i(\Omega_i) \cap \tau_j(\Omega_j) = \tau_i(\Omega_{ij}) = \tau_j(\Omega_{ji}).
\]
Finally, assume that \((i, j) \in K\). Then, for any \(x \in \Omega_{ij} \subseteq \Omega_i\), we have \(y = \varphi_{ji}(x) \in \Omega_j \subseteq \Omega_j\) and \(x \sim y\), so that \(\tau_i(x) = \tau_j(y)\), which proves that \(\tau_i(\Omega_i) \cap \tau_j(\Omega_j) \neq \emptyset\). So, our claim is true, and we can use it.

We now prove that the topology of \(M_G\) is Hausdorff. Pick \([x], [y] \in M_G\) with \([x] \neq [y]\), for some \(x \in \Omega_i\) and some \(y \in \Omega_j\). Either \(\tau_i(\Omega_i) \cap \tau_j(\Omega_j) = \emptyset\), in which case, as \(\tau_i\) and \(\tau_j\) are homeomorphisms, \([x]\) and \([y]\) belong to the two disjoint open sets \(\tau_i(\Omega_i)\) and \(\tau_j(\Omega_j)\). If not, then by the Claim, \((i, j) \in K\) and

\[
\tau_i(\Omega_i) \cap \tau_j(\Omega_j) = \tau_i(\Omega_{ij}) = \tau_j(\Omega_{ji}).
\]

There are several cases to consider (refer to Figure 3.4):

1. If \(i = j\) then \(x\) and \(y\) can be separated by disjoint opens, \(V_x\) and \(V_y\), and as \(\tau_i\) is a homeomorphism, \([x]\) and \([y]\) are separated by the disjoint open subsets \(\tau_i(V_x)\) and \(\tau_j(V_y)\).

2. If \(i \neq j\), \(x \in \Omega_i - \Omega_{ij}\) and \(y \in \Omega_j - \Omega_{ji}\), then \(\tau_i(\Omega_i - \Omega_{ij})\) and \(\tau_j(\Omega_j - \Omega_{ji})\) are disjoint open subsets separating \([x]\) and \([y]\), where \(\Omega_{ij}\) and \(\Omega_{ji}\) are the closures of \(\Omega_{ij}\) and \(\Omega_{ji}\), respectively.

3. If \(i \neq j\), \(x \in \Omega_{ij}\) and \(y \in \Omega_{ji}\), as \([x] \neq [y]\) and \(y \sim \varphi_{ij}(y)\), then \(x \neq \varphi_{ij}(y)\). We can separate \(x\) and \(\varphi_{ij}(y)\) by disjoint open subsets, \(V_x\) and \(V_y\), and \([x]\) and \([y] = [\varphi_{ij}(y)]\) are separated by the disjoint open subsets \(\tau_i(V_x)\) and \(\tau_i(V_y)\).

4. If \(i \neq j\), \(x \in \partial(\Omega_{ij}) \cap \Omega_i\) and \(y \in \partial(\Omega_{ji}) \cap \Omega_j\), then we use condition 4 of Definition 3.1. This condition yields two disjoint open subsets, \(V_x\) and \(V_y\), with \(x \in V_x\) and \(y \in V_y\), such that no point of \(V_x \cap \Omega_{ij}\) is equivalent to any point of \(V_y \cap \Omega_{ji}\), and so \(\tau_i(V_x)\) and \(\tau_j(V_y)\) are disjoint open subsets separating \([x]\) and \([y]\).

Therefore, the topology of \(M_G\) is Hausdorff and \(M_G\) is indeed a manifold. Finally, it is trivial to verify that the transition maps of \(M_G\) are the original gluing functions, \(\varphi_{ij}\), since \(\varphi_i = \tau_i^{-1}\) and \(\varphi_{ji} = \varphi_j \circ \varphi_i^{-1}\).

In what follows, we show that condition 4 (the Hausdorff condition) of Definition 3.1 is necessary, and we also show that the cocycle condition given by Grimm in [12, 27] does not ensure the transitivity of \(\sim\).
Consider the open intervals $\Omega_1 = (-3, -1)$, $\Omega_2 = (1, 3)$, $\Omega_{12} = (-3, -2)$, and $\Omega_{21} = (2, 1)$ in $\mathbb{R}$, and let $\varphi_{21}(x) = x + 4$ and $\varphi_{12}(x) = x - 4$ be the gluing functions that identify $\Omega_{12}$ and $\Omega_{21}$. The space, $C$, resulting from this gluing data is a curve looking like a “fork”. Note that the gluing data does not satisfy condition 4 of Definition 3.1 for $x = -2$ in $\partial(\Omega_{12}) \cap \Omega_1$ and $y = 2$ in $\partial(\Omega_{21}) \cap \Omega_2$. But, the images of $-2$ and $2$ in $C$ cannot be separated, as the images in $C$ of any two open intervals $(-2 - \varepsilon, -2 + \varepsilon)$ and $(2 - \eta, 2 + \eta)$, with $\varepsilon, \eta > 0$, always intersect since $(-2 - \min(\varepsilon, \eta), -2)$ and $(2 - \min(\varepsilon, \eta), 2)$ are identified. So, $C$ is not a Hausdorff space, and thus condition 4 is indeed necessary.

Grimm [27] (page 40) uses a condition stronger than our condition 4 to ensure that the quotient, $M_G$, is Hausdorff, namely, that for all $(i, j) \in K$ with $i \neq j$, the quotient $(\Omega_i \coprod \Omega_j)/\sim$ should be embeddable in $\mathbb{R}^n$. This is a rather stronger condition, which for instance prevents us from obtaining a 2-sphere by gluing two open discs in $\mathbb{R}^2$ along an annulus (see Grimm [27], Appendix C2, page 126).

Finally, the cocycle condition given by Grimm in [27] (page 40) and [12] (page 361) is stated as follows:

\begin{itemize}
  \item [(c')] For all $x \in \Omega_{ij} \cap \Omega_{ik}$,
    \[ \varphi_{ki}(x) = \varphi_{kj} \circ \varphi_{ji}(x). \]
\end{itemize}

This condition is not strong enough to imply transitivity of the relation $\sim$. In fact, consider the open intervals $\Omega_1 = (0, 3)$, $\Omega_2 = (4, 5)$, $\Omega_3 = (6, 9)$, $\Omega_{12} = (0, 1)$, $\Omega_{13} = (2, 3)$, $\Omega_{21} = \Omega_{23} = (4, 5)$, $\Omega_{32} = (8, 9)$, and $\Omega_{31} = (6, 7)$ in $\mathbb{R}$, and the gluing functions $\varphi_{21}(x) = x + 4$, $\varphi_{32}(x) = x + 4$, and $\varphi_{31}(x) = x + 4$. Note that the pairwise gluing yields Hausdorff spaces. Clearly, $\varphi_{32} \circ \varphi_{21}(x) = x + 8$, for all $x \in \Omega_{12}$, but $\Omega_{12} \cap \Omega_{13} = \emptyset$. So, we get $0.5 \sim 4.5 \sim 8.5$, but $0.5 \not\sim 8.5$ since $\varphi_{31}(0.5)$ is undefined.

**Remark 3.2.** Readers familiar with fibre bundles may wonder why the cocycle condition 3c of Definition 3.1 is more arcane than the corresponding definition found in bundle theory. The reason is that if $\pi : E \to B$ is a (smooth or $C^k$) fibre bundle with fibre, $F$, then there is some open cover, $(U_\alpha)$, of the base space, $B$, and for every index, $\alpha$, there is a local trivialization map, namely a diffeomorphism,

\[ \varphi_\alpha : \pi^{-1}(U_\alpha) \to U_\alpha \times F, \]
such that
\[ \pi = p_1 \circ \varphi_\alpha, \]
where \( p_1 : U_\alpha \times F \rightarrow U_\alpha \) is the projection onto \( U_\alpha \). Then, whenever \( U_\alpha \cap U_\beta \neq \emptyset \), we have a map
\[ \varphi_\alpha \circ \varphi_\beta^{-1} : (U_\alpha \cap U_\beta) \times F \rightarrow (U_\alpha \cap U_\beta) \times F, \]
and because \( \pi = p_1 \circ \varphi_\alpha \) for all \( \alpha \), there is a map,
\[ g_{\beta \alpha} : U_\alpha \cap U_\beta \rightarrow \text{Diff}(F), \]
where \( \text{Diff}(F) \) denotes the group of diffeomorphisms of the fibre, \( F \), such that
\[ \varphi_\alpha \circ \varphi_\beta^{-1}(b, p) = (b, g_{\beta \alpha}(b)(p)), \]
for all \( b \in U_\alpha \cap U_\beta \) and all \( p \in F \). The maps, \( g_{\beta \alpha} \), are the transition maps of the bundle. Observe that for all \( b \in U_\alpha \cap U_\beta \), the maps, \( g_{\beta \alpha}(b) \), have the same domain and the same range, \( F \). So, whenever \( U_\alpha \cap U_\beta \cap U_\gamma \neq \emptyset \), for all \( b \in U_\alpha \cap U_\beta \cap U_\gamma \), the maps \( g_{\beta \alpha} \), \( g_{\gamma \beta} \) and \( g_{\gamma \alpha} \) have the same domain and the same range. Consequently, in this case, the cocycle condition can be simply stated as
\[ g_{\gamma \alpha} = g_{\gamma \beta} \circ g_{\beta \alpha}, \]
without taking any precautions about the domains of these maps. However, in our situation (a manifold), the transition maps are of the form \( \varphi_{ji} : \Omega_{ij} \rightarrow \Omega_{ji} \), where the \( \Omega_{ij} \) are various unrelated open subsets of \( \mathbb{R}^n \), and so, the composite map, \( \varphi_{kj} \circ \varphi_{ji} \) only makes sense on a subset of \( \Omega_{ij} \) (the domain of \( \varphi_{ji} \)). However, this subset need not be contained in the domain of \( \varphi_{ki} \). So, in order to avoid the extra complications we saw before, the constraints in condition 3c of Definition 3.1 must be imposed.

**Remark 3.3.** In reconstructing a fibre bundle from \( B \) and the transition maps, \( g_{\beta \alpha} \), we use the \( g_{\beta \alpha} \) to glue the spaces \( U_\alpha \times F \) and \( U_\beta \times F \) along \( (U_\alpha \cap U_\beta) \times F \), where two points \( (a, p) \) and \( (b, q) \) in \( (U_\alpha \cap U_\beta) \times F \) are identified iff \( a = b \) and \( q = g_{\beta \alpha}(a)(p) \). In reconstructing a manifold from a set of gluing data, we glue the open sets \( \Omega_i \) and \( \Omega_j \) along \( \Omega_{ij} \) and \( \Omega_{ji} \), which are identified using the maps, \( \varphi_{ji} \).
4 Manifolds from sets of gluing data

The proof of Theorem 3.1 gives us a theoretical construction, which yields an “abstract” manifold, \( M_G \), but does not yield any information on the geometry of this manifold. In addition, the manifold \( M_G \) may not be orientable nor compact, even if we start with a finite set of \( p \)-domains. In practice, we often need a compact and orientable manifold embedded in \( \mathbb{R}^n \), for some small integer \( n \), with a prescribed geometry. In this section, we define such a “concrete” manifold from a set of gluing data.

Given a set of gluing data
\[
\mathcal{G} = \left\{ (\Omega_i)_{i \in I}, (\Omega_{ij})_{(i,j) \in I \times I}, (\varphi_{ji})_{(i,j) \in K} \right\},
\]

it is natural to consider the collection of manifolds, \( M \), parametrized by maps
\[
\theta_i : \Omega_i \to M,
\]
whose domains are the \( \Omega_i \)'s and whose transition maps are given by the \( \varphi_{ji} \)'s, that is, such that
\[
\varphi_{ji} = \theta_j^{-1} \circ \theta_i.
\]

We say that such manifolds are induced by the set of gluing data, \( \mathcal{G} \). Figure 4.1 illustrates this notion.

Recall from the proof of Theorem 3.1 that the parametrization maps, \( \tau_i \)'s, satisfy the condition
\[
\tau_i(\Omega_i) \cap \tau_j(\Omega_j) \neq \emptyset
\]
iff \((i, j) \in K\), and if so,
\[
\tau_i(\Omega_i) \cap \tau_j(\Omega_j) = \tau_i(\Omega_{ij}) = \tau_j(\Omega_{ji}).
\]
Furthermore, they also satisfy the consistency condition,
\[
\tau_i = \tau_j \circ \varphi_{ji},
\]
for all \((i, j) \in K\). If \( M \) is a manifold induced by the set of gluing data, \( \mathcal{G} \), because the \( \theta_i \)'s are injective maps and \( \varphi_{ji} = \theta_j^{-1} \circ \theta_i \), the two properties stated above for the \( \tau_i \)'s also hold for the \( \theta_i \)'s. In practice, however, it is often hard to ensure injectivity of the \( \theta_i \)'s [18]. Fortunately, we can still
Figure 3.4: The four cases of the proof of Condition 4 of Definition 3.1.

Figure 4.1: A manifold induced from a set of gluing data.
define a useful class of spaces from gluing data and parametrization maps that are not necessarily injective. Roughly speaking, the gluing data specify the topology and the parametrizations define the geometry of the space. These spaces, called *parametric pseudo-manifolds* (or simply, PPMs), are not quite manifolds, but they have successfully been used as such in several applications [28, 5, 29, 19].

### 4.1 Parametric pseudo-manifolds

Parametric pseudo-manifolds are topological spaces induced from gluing data which have two distinguishing properties: they are embedded in $\mathbb{R}^d$, for some positive integer $d$, i.e., the image of each parametrization map is a subset of $\mathbb{R}^d$, and the parametrization maps themselves are not necessarily injective.

**Definition 4.1.** Let $n$, $d$, and $k$ be three integers with $d > n \geq 1$ and $k \geq 1$ or $k = \infty$. A *parametric $C^k$ pseudo-manifold of dimension $n$ in $\mathbb{R}^d$* (for short, *parametric pseudo-manifold* or PPM) is a pair,

$$\mathcal{M} = (\mathcal{G}, (\theta_i)_{i \in I}) ,$$

such that

$$\mathcal{G} = \left( (\Omega_i)_{i \in I}, (\Omega_{ij})_{(i,j) \in I \times I}, (\varphi_{ji})_{(i,j) \in K} \right)$$

is a set of gluing data, for some finite set $I$, and each $\theta_i$ is a $C^k$ function, $\theta_i : \Omega_i \to \mathbb{R}^d$, that satisfies

(C) For all $(i,j) \in K$, we have

$$\theta_i = \theta_j \circ \varphi_{ji} .$$

We call $\theta_i$ a *parametrization*. The subset, $M \subset \mathbb{R}^d$, given by

$$M = \bigcup_{i \in I} \theta_i(\Omega_i)$$

is called the *image* of the parametric pseudo-manifold, $\mathcal{M}$. Whenever $n = 2$ and $d = 3$, we say that $\mathcal{M}$ is a *parametric pseudo-surface* (or PPS, for short), and that $M$, the image of $\mathcal{M}$, is a *pseudo-surface*. 

20
Condition C obviously implies that
\[ \theta_i(\Omega_{ij}) = \theta_j(\Omega_{ji}) , \]
for all \((i, j) \in K\). Consequently, \(\theta_i\) and \(\theta_j\) are consistent parametrizations of the overlap \(\theta_i(\Omega_{ij}) = \theta_j(\Omega_{ij})\). Thus, the set \(M\), whatever it is, is covered by pieces, \(U_i = \theta_i(\Omega_i)\), not necessarily open, such that each \(U_i\) is parametrized by \(\theta_i\), and each overlapping piece, \(U_i \cap U_j\), is parametrized consistently.

The local structure of \(M\) is given by the \(\theta_i\)’s and its global structure is given by the gluing data. More importantly, we can equip \(M\) with a manifold structure if we require the \(\theta_i\)’s to be injective and to satisfy

\[(C') \text{ For all } (i, j) \in K, \quad \theta_i(\Omega_i) \cap \theta_j(\Omega_j) = \theta_i(\Omega_{ij}) = \theta_j(\Omega_{ji}) .\]

\[(C'') \text{ For all } (i, j) \notin K, \quad \theta_i(\Omega_i) \cap \theta_j(\Omega_j) = \emptyset .\]

Even if the \(\theta_i\)’s are not injective, properties \(C’\) and \(C''\) are still desirable since they ensure that \(\theta_i(\Omega_i - \Omega_{ij})\) and \(\theta_j(\Omega_j - \Omega_{ji})\) are uniquely parametrized. Unfortunately, properties \(C’\) and \(C''\) seem to be difficult to enforce in practice (at least for surface constructions based on the gluing process \([12, 14, 15, 17, 18]\)). Interestingly, regardless whether conditions \(C’\) and \(C''\) are satisfied, we can still show that \(M\) is the image in \(\mathbb{R}^d\) of the abstract manifold, \(M_G\), as stated by Proposition 4.1 below:

**Proposition 4.1.** Let \(\mathcal{M} = (\mathcal{G}, (\theta_i)_{i \in I})\) be a parametric \(C^k\) pseudo-manifold of dimension \(n\) in \(\mathbb{R}^d\), where \(\mathcal{G} = ((\Omega_i)_{i \in I}, (\Omega_{ij})_{(i,j) \in I \times I}, (\varphi_{ji})_{(i,j) \in K})\) is a set of gluing data, for some finite set \(I\). Then, the parametrization maps, \(\theta_i\), induce a surjective map, \(\Theta: M_G \to M\), from the abstract manifold, \(M_G\), specified by \(\mathcal{G}\) to the image, \(M \subseteq \mathbb{R}^d\), of the parametric pseudo-manifold, \(\mathcal{M}\), and the following property holds:
\[ \theta_i = \Theta \circ \tau_i , \]
for every \(\Omega_i\), where \(\tau_i: \Omega_i \to M_G\) are the parametrization maps of the manifold \(M_G\) (see Theorem 3.1). In particular, every manifold, \(M \subset \mathbb{R}^d\), such that \(M\) is induced by \(\mathcal{G}\) is the image of \(M_G\) by a map
\[ \Theta: M_G \to M .\]
Proof. Recall that

\[ M_G = \left( \coprod_{i \in I} \Omega_i \right) / \sim, \]

where \( \sim \) is the equivalence relation defined so that, for all \( x, y \in \coprod_{i \in I} \Omega_i \),

\[ x \sim y \iff (\exists (i, j) \in K)(x \in \Omega_{ij}, y \in \Omega_{ji}, y = \varphi_{ji}(x)). \]

From the proof of Theorem 3.1, we have that \( \tau_i(\Omega_i) \cap \tau_j(\Omega_j) \neq \emptyset \) iff \( (i, j) \in K \) and if so,

\[ \tau_i(\Omega_i) \cap \tau_j(\Omega_j) = \tau_i(\Omega_{ij}) = \tau_j(\Omega_{ji}). \]

In particular,

\[ \tau_i(\Omega_i - \Omega_{ij}) \cap \tau_j(\Omega_j - \Omega_{ji}) = \emptyset \]

for all \( (i, j) \in I \times I \) \( (\Omega_{ij} = \Omega_{ji} = \emptyset \) when \( (i, j) \notin K \)). These properties with the fact that the \( \tau_i \)'s are injections show that for all \( (i, j) \notin K \), we can define \( \Theta_i : \tau_i(\Omega_i) \to \mathbb{R}^d \) and \( \Theta_j : \tau_j(\Omega_j) \to \mathbb{R}^d \) by

\[ \Theta_i([x]) = \theta_i(x), \ x \in \Omega_i - \Omega_{ij} \quad \text{and} \quad \Theta_j([y]) = \theta_j(y), \ y \in \Omega_j - \Omega_{ji}. \]

It remains to define \( \Theta_i \) on \( \tau_i(\Omega_{ij}) \) and \( \Theta_j \) on \( \tau_j(\Omega_{ji}) \) in such a way that they agree on \( \tau_i(\Omega_{ij}) = \tau_j(\Omega_{ji}) \). However, condition C in Definition 4.1 says that for all \( x \in \Omega_{ij}, \theta_i(x) = \theta_j(\varphi_{ji}(x)). \) Consequently, if we define \( \Theta_i \) on \( \tau_i(\Omega_{ij}) \) and \( \Theta_j \) on \( \tau_j(\Omega_{ji}) \) by

\[ \Theta_i([x]) = \theta_i(x), \ x \in \Omega_{ij} \quad \text{and} \quad \Theta_j([y]) = \theta_j(y), \ y \in \Omega_{ji}, \]

as \( x \sim \varphi_{ji}(x) \), we have

\[ \Theta_i([x]) = \theta_i(x) = \theta_j(\varphi_{ji}(x)) = \Theta_j([\varphi_{ji}(x)]) = \Theta_j([x]), \]

which means that \( \Theta_i \) and \( \Theta_j \) agree on \( \tau_i(\Omega_{ij}) = \tau_j(\Omega_{ji}) \). But then, the functions, \( \Theta_i \), agree whenever their domains overlap and consequently, they patch to yield a function, \( \Theta \), with domain \( M_G \) and image \( M \), as desired. Finally, since \( \theta_i = \Theta \circ \tau_i \) (by construction), and since any manifold in \( \mathbb{R}^d \) induced by \( G \) is a PPM, every manifold, \( M \), in \( \mathbb{R}^d \) induced by \( G \) is the image of \( M_G \) by a map \( \Theta : M_G \to M \).
4.2 Equivalence of gluing data and isomorphic manifolds

To end our discussion on the definition of manifolds from gluing data, we show that it is possible to characterize isomorphism between two manifolds induced by the same set of gluing data in terms of a condition on their transition maps. This characterization suggests a notion of equivalence on sets of gluing data. It turns out that manifolds induced by two equivalent sets of gluing data are isomorphic.

**Proposition 4.2.** Given any set of gluing data,

\[ G = ((\Omega_i)_{i \in I}, (\Omega_{ij})_{(i,j) \in I \times I}, (\varphi_{ji})_{(i,j) \in K}) \]

for any two manifolds \( M \) and \( M' \) induced by \( G \) given by families of parametrizations \((\Omega_i, \theta_i)_{i \in I}\) and \((\Omega_i, \theta'_i)_{i \in I}\), respectively, if \( f : M \to M' \) is a \( C^k \) isomorphism, then there are \( C^k \) bijections,

\[ \rho_i : W_{ij} \to W'_{ij}, \]

for some open subsets \( W_{ij}, W'_{ij} \subseteq \Omega_i \), such that

\[ \varphi'_{ji}(x) = \rho_j \circ \varphi_{ji} \circ \rho_i^{-1}(x), \quad \text{for all } x \in W_{ij}, \]

with \( \varphi_{ji} = \theta_j^{-1} \circ \theta_i \) and \( \varphi'_{ji} = \theta'_j^{-1} \circ \theta'_i \). Furthermore, \( \rho_i = (\theta'^{-1}_i \circ f \circ \theta_i) \mid W_{ij} \) and if \( \theta'^{-1}_i \circ f \circ \theta_i \) is a bijection from \( \Omega_i \) to itself and \( \theta'^{-1}_i \circ f \circ \theta_i(\Omega_{ij}) = \Omega_{ij} \), for all \( i, j \), then \( W_{ij} = W'_{ij} = \Omega_i \).

**Proof.** The composition \( \theta'^{-1}_i \circ f \circ \theta_i \) is actually a partial function with domain

\[ \text{dom}(\theta'^{-1}_i \circ f \circ \theta_i) = \{ x \in \Omega_i \mid \theta_i(x) \in f^{-1} \circ \theta_i(\Omega_i) \} \]

and its “inverse” \( \theta_i^{-1} \circ f^{-1} \circ \theta'_i \) is a partial function with domain

\[ \text{dom}(\theta_i^{-1} \circ f^{-1} \circ \theta'_i) = \{ x \in \Omega_i \mid \theta'_i(x) \in f \circ \theta_i(\Omega_i) \}. \]

The composition \( \theta'^{-1}_i \circ f \circ \theta_j \circ \varphi_{ji} \circ \theta_i^{-1} \circ f^{-1} \circ \theta'_i \) is also a partial function and we let

\[ W_{ij} = \Omega_{ij} \cap \text{dom}(\theta'^{-1}_j \circ f \circ \theta_j \circ \varphi_{ji} \circ \theta_i^{-1} \circ f^{-1} \circ \theta'_i), \quad \rho_i = (\theta'^{-1}_i \circ f \circ \theta_i) \mid W_{ij}, \quad \text{and } W'_{ij} = \rho_i(W_{ij}). \]

Observe that \( \theta_j \circ \varphi_{ji} = \theta_j \circ \theta^{-1}_j \circ \theta_i = \theta_i \); that is,

\[ \theta_i = \theta_j \circ \varphi_{ji}. \]
Using this, on $W_{ij}$, we get
\[
\rho_j \circ \varphi_{ji} \circ \rho_i^{-1} = \theta_j^{-1} \circ f \circ \theta_j \circ \varphi_{ji} \circ \theta_i^{-1} \circ f \circ \theta_i^{-1} = \theta_j^{-1} \circ f \circ \theta_j \circ \varphi_{ji} \circ \theta_i^{-1} \circ f^{-1} \circ \theta_i' = \theta_j^{-1} \circ f \circ \theta_i^{-1} \circ f^{-1} \circ \theta_i' = \theta_j^{-1} \circ \theta_i' = \varphi'_{ji},
\]
as claimed. The last part of the proposition is clear.

Proposition 4.2 suggests defining the following notion of equivalence on sets of gluing data:

**Definition 4.2.** Two sets of gluing data,
\[
\mathcal{G} = \left( (\Omega_i)_{i \in I}, (\Omega_{ij})_{(i,j) \in I \times I}, (\varphi_{ji})_{(i,j) \in K} \right) \quad \text{and} \quad \mathcal{G}' = \left( (\Omega_i)_{i \in I}, (\Omega_{ij})_{(i,j) \in I \times I}, (\varphi'_{ji})_{(i,j) \in K} \right),
\]
over the same $p$-domains and gluing domains, $\Omega_i$’s and $\Omega_{ij}$’s, are **equivalent** iff there is a family of $C^k$ bijections,
\[
(\rho_i : \Omega_i \to \Omega_i)_{i \in I}
\]
such that for all $i, j \in I$ and for all $x \in \Omega_{ij},$
\[
\rho_i(\Omega_{ij}) = \Omega_{ij} \quad \text{and} \quad \varphi'_{ji}(x) = \rho_j \circ \varphi_{ji} \circ \rho_i^{-1}(x).
\]

Based on the notion of equivalence of gluing data given by Definition 4.2, we prove the converse of Proposition 4.2:

**Proposition 4.3.** If two sets of gluing data,
\[
\mathcal{G} = \left( (\Omega_i)_{i \in I}, (\Omega_{ij})_{(i,j) \in I \times I}, (\varphi_{ji})_{(i,j) \in K} \right) \quad \text{and} \quad \mathcal{G}' = \left( (\Omega_i)_{i \in I}, (\Omega_{ij})_{(i,j) \in I \times I}, (\varphi'_{ji})_{(i,j) \in K} \right),
\]
are equivalent, then there is a $C^k$ isomorphism, $f : M_\mathcal{G} \to M_{\mathcal{G}'}$, between the manifolds induced by $\mathcal{G}$ and $\mathcal{G}'$. Furthermore,
\[
f \circ \tau_i = \tau'_i \circ \rho_i,
\]
for all $i \in I$. 

24
Proof. Let \( f_i : \tau_i(\Omega_i) \rightarrow \tau'_i(\Omega_i) \) be the \( C^k \) bijection given by

\[
f_i = \tau'_i \circ \rho_i \circ \tau^{-1}_i,
\]

where the \( \rho_i : \Omega_i \rightarrow \Omega_i \)'s are the maps giving the equivalence of \( \mathcal{G} \) and \( \mathcal{G}' \). If we prove that \( f_i \) and \( f_j \) agree on the overlap, \( \tau_i(\Omega_i) \cap \tau_j(\Omega_j) = \tau_i(\Omega_{ij}) \cap \tau_j(\Omega_{ji}) \), then the \( f_i \) patch and yield a \( C^k \) isomorphism, \( f : M_\mathcal{G} \rightarrow M_{\mathcal{G}'} \). Since \( \mathcal{G} \) and \( \mathcal{G}' \) are equivalent, we know that

\[
\varphi'_{ji} \circ \rho_i = \rho_j \circ \varphi_{ji}.
\]

But, we also know that

\[
\tau'_i = \tau'_j \circ \varphi'_{ji}.
\]

Consequently, for every \([x] \in \tau_j(\Omega_{ji}) = \tau_i(\Omega_{ij})\), with \( x \in \Omega_{ij} \), we have

\[
f_j([x]) = \tau'_j \circ \rho_j \circ \tau^{-1}_j([x]) = \tau'_j \circ \rho_j \circ \tau^{-1}_j([\varphi_{ji}(x)]) = \tau'_j \circ \rho_j \circ \varphi_{ji}(x) = \tau'_j \circ \varphi'_{ji} \circ \rho_i(x) = \tau'_i \circ \rho_i(x) = \tau'_i \circ \rho_i \circ \tau^{-1}_i([x]) = f_i([x]),
\]

which shows that \( f_i \) and \( f_j \) agree on \( \tau_i(\Omega_i) \cap \tau_j(\Omega_j) \), as claimed. \( \Box \)

5 Building a “concrete” set of gluing data

5.1 Informal Description of the Method

This section gives an informal description of the method for building a “concrete” set of gluing data from a given simplicial surface in \( \mathbb{R}^3 \). Such a surface is known as a “triangle mesh” in the context of graphics applications. We also try to describe the problems that we ran into during this process and motivate the decisions that we made to overcome these difficulties. Our construction uses the connectivity information of the given simplicial surface to define the set of gluing data.
Figure 5.1: Top: The star of a vertex on a simplicial surface. Bottom: Two overlapping stars on a simplicial surface.
In [18], we show how to define a PPM from this set of gluing data. Suppose you are flying over a simplicial surfaces (for short, mesh). Looking down at the mesh, around every vertex $u$, we see a star of triangles, as illustrated in Figure 5.1. Furthermore, for every pair of adjacent vertices $u$ and $w$, there are two stars that overlap is a (generally nonflat) quadrangle consisting of two triangles sharing the edge $[u, w]$, as shown in Figure 5.1. Thus, it is natural to associate to every vertex of our mesh $u$ a $p$-domain $\Omega_u$, which is a flattened version of the star of $u$, namely the interior of a regular polygon of radius $\cos(\pi/m_u)$, where $m_u$ is the degree of $u$. There is a natural piecewise affine map $s_u$ which maps the star of $u$ to that $p$-domain, so that the image of every point $v$ on the star of $u$ is $s_u(v)$. In particular, $s_u(u)$ is the center of $\Omega_u$. Now, given two adjacent vertices $u$ and $w$ on the mesh, the overlap of the stars of $u$ and $w$ is a quadrangle, say $[u, v, w, z]$, and this quadrangle corresponds to the two quadrangles $[s_u(u), s_u(v), s_u(w), s_u(z)]$ in $\Omega_u$, and $[s_w(w), s_w(z), s_w(u), s_w(v)]$ in $\Omega_w$ (see Figure 5.2).

It is then natural to let $\Omega_{uw}$ be the interior of $[s_u(u), s_u(v), s_u(w), s_u(z)]$ and $\Omega_{wu}$ be the interior of $[s_w(w), s_w(z), s_w(u), s_w(v)]$. To simplify notation, we assume that some vertex $u_0$ is chosen on the star of $u$, we denote the vertices of the star by $u_0, \ldots, u_{m_u-1}$ (listed according to some traversal of the star), and we denote $s_u(u_i)$ by $u'_i$. We also denote $s_u(u)$ by $u'$.  

Now, the problem is to define transition maps $\varphi_{wu} : \Omega_{uw} \to \Omega_{wu}$ which are smooth diffeomorphisms there is no explicit formula that satisfy the cocycle condition. Furthermore, we would like the $\varphi_{wu}$ to be easily computable. Since $\Omega_{uw}$ and $\Omega_{wu}$ are bounded open subset of the plane, at first glance, it would appear that the problem is solved by appealing to the Riemann mapping Theorem.

![Figure 5.2: Two $p$-domains corresponding to overlapping stars](image)
(see Ahlfors [30], Chapter 6, Section 1.1). However, there is no closed-form formula giving the Riemann mapping for quadrangles; instead, a conformal diffeomorphism is given by the Schwarz-Christoffel formula, which involves an integral (see Ahlfors [30], Chapter 6, Section 2.2). Worse, we haven’t been able to prove that such a formula yields a diffeomorphism which satisfies the cocycle condition, and this appears difficult.

In view of the above considerations, we will seek an approach where we modify the open subsets $\Omega_u$ and $\Omega_{uw}$ a little bit. But first, we can simplify the problem of finding the smooth diffeomorphisms $\varphi_{wu}$ by reducing it to finding a diffeomorphism between a quadrangle whose angle at the origin is $4\pi/m_u$ and the canonical diamond $Q$, consisting of two equilateral triangles, whose vertices are $(0, 0), (1/2, -\sqrt{3}/2), (1, 0), (1/2, \sqrt{3}/2)$; see Figure 5.3.

![Figure 5.3: The canonical diamond $Q$](image)

Let $R_{(u,w)}$ be the rotation of center $(0, 0)$ which maps the edge $[u', s_u(w)]$ onto the edge $[u', u'_0]$. Now, rotate the quadrilateral $[s_u(u), s_u(v), s_u(w), s_u(z)]$ in $\Omega_u$ using $R_{(u,w)}$, obtaining the quadrilateral $[u', u'_{m_u-1}, u'_0, u'_1]$ that “stands upright.” At this stage, assume that we are in the possession of a diffeomorphism $g_u$ that maps the interior of $[u', u'_{m_u-1}, u'_0, u'_1]$ to the interior of the canonical diamond $Q$; see Figure 5.4.

Similarly, we can rotate the quadrilateral $[s_w(w), s_w(z), s_w(u), s_w(v)]$ in $\Omega_w$ by the rotation $R_{(w,u)}$, obtaining the quadrilateral $[w', w'_{m_w-1}, w'_0, w'_1]$, and then map this quadrilateral into the canonical diamond $Q$ using $g_w$; see Figure 5.5.

However, observe that because under the rotation $R_{(u,w)}$ the vertex $v$ goes to $u'_{m_u-1}$ (resp. the vertex $z$ goes to $u'_1$), and under the rotation $R_{(w,u)}$ the vertex $v$ goes to $w'_1$ (resp. the vertex $z$ goes
to \( u'_{m-1} \), which means that the images of \( v \) and \( z \) under the rotations \( R_{(u,w)} \) and \( R_{(w,u)} \) are flipped, and similarly for the images of \( u \) and \( w \).

The solution is simple: in order for \( g_u \circ R_{(u,w)} \) and \( g_w \circ R_{(w,u)} \) to yield the same result, rotate \( Q \) by \( \pi \) around the point \((1/2, 0)\). Let \( h \) denote this rotation.

In summary, we can define our diffeomorphism \( \varphi_{wu} \) by

\[
\varphi_{wu} = R^{-1}_{(w,u)} \circ g_w^{-1} \circ h \circ g_u \circ R_{(u,w)},
\]

with \( \varphi_{wu} = \text{id} \); see Figure 5.6.

The problem is reduced to finding diffeomorphisms \( g_u \) that satisfy the cocycle condition. Thus,
Figure 5.6: The transition function $\varphi_{wu}$
we have to show that
\[ \varphi_{wu} = \varphi_{wx} \circ \varphi_{xu}, \]
whenever the right-hand side is defined (which turns out to imply that the left-hand side is also defined). Since
\[
\begin{align*}
\varphi_{wu} &= R_{(w,u)}^{-1} \circ g_w^{-1} \circ h \circ g_u \circ R_{(u,w)} \\
\varphi_{xu} &= R_{(x,u)}^{-1} \circ g_x^{-1} \circ h \circ g_u \circ R_{(u,x)} \\
\varphi_{wx} &= R_{(w,x)}^{-1} \circ g_w^{-1} \circ h \circ g_x \circ R_{(x,w)},
\end{align*}
\]
we get
\[
\varphi_{wx} \circ \varphi_{xu} = R_{(w,x)}^{-1} \circ g_w^{-1} \circ h \circ g_x \circ R_{(x,w)} \circ R_{(x,u)}^{-1} \circ g_x^{-1} \circ h \circ g_u \circ R_{(u,x)}
\]
and we have to show that this is equal to \( \varphi_{wu} = R_{(w,u)}^{-1} \circ g_w^{-1} \circ h \circ g_u \circ R_{(u,w)} \).

Without loss of generality, suppose that \( s_u(x) \) follows \( s_u(w) \) in a counterclockwise traversal. This means that \( s_w(u) \) follows \( s_w(x) \) in a counterclockwise traversal, and that \( s_x(w) \) follows \( s_x(u) \) in a counterclockwise traversal. First, note that
\[
R_{(x,w)} \circ R_{(x,u)}^{-1} = M_{-\frac{2\pi}{m_x}},
\]
where \( M_{-\frac{2\pi}{m_x}} \) is the rotation of center \((0,0)\) and angle \(-2\pi/m_x\), as \( s_x(w) \) follows \( s_x(u) \) in a counterclockwise traversal, where \( m_x \) is the degree of \( x \). We get
\[
\varphi_{wx} \circ \varphi_{xu} = R_{(w,x)}^{-1} \circ g_w^{-1} \circ h \circ g_x \circ M_{-\frac{2\pi}{m_x}} \circ g_x^{-1} \circ h \circ g_u \circ R_{(u,x)}.
\]
In order to make progress, it would be nice if we could simplify the middle term \( g_x \circ M_{-\frac{2\pi}{m_x}} \circ g_x^{-1} \).

In fact, if we look at Figure 5.7, we see that it would be desirable to assume that
\[
g_x \circ M_{-\frac{2\pi}{m_x}} \circ g_x^{-1} = M_{-\frac{\pi}{3}}, \quad (\text{A})
\]
where \( M_{-\frac{\pi}{3}} \) is the rotation of center \((0,0)\) and angle \(-\pi/3\). If we do so, we get
\[
R_{(w,x)}^{-1} \circ g_w^{-1} \circ h \circ g_x \circ M_{-\frac{2\pi}{m_x}} \circ g_x^{-1} \circ h \circ g_u \circ R_{(u,x)} = R_{(w,x)}^{-1} \circ g_w^{-1} \circ h \circ M_{-\frac{\pi}{3}} \circ h \circ g_u \circ R_{(u,x)}.
\]
We seem to be stuck, but it turns out that property (A) implies that that
\[
g_u \circ R_{(u,x)} = M_{-\frac{\pi}{3}} \circ g_u \circ R_{(u,w)}, \quad (\text{B})
\]
Figure 5.7: Property (A)
as shown in Proposition 5.1. Similarly, we have

\[ g_w \circ R_{(w,x)} = M_{\frac{\pi}{3}} \circ g_w \circ R_{(w,u)}. \]

Using these equations, we get

\[
R_{(w,x)}^{-1} \circ g_w^{-1} \circ h \circ M_{-\frac{\pi}{3}} \circ h \circ g_u \circ R_{(u,x)} = R_{(w,u)}^{-1} \circ g_w^{-1} \circ M_{-\frac{\pi}{3}} \circ h \circ M_{-\frac{\pi}{3}} \circ h \circ M_{-\frac{\pi}{3}} \circ g_u \circ R_{(u,w)},
\]

so

\[
\varphi_{wx} \circ \varphi_{xu} = R_{(w,u)}^{-1} \circ g_w^{-1} \circ M_{-\frac{\pi}{3}} \circ h \circ M_{-\frac{\pi}{3}} \circ h \circ M_{-\frac{\pi}{3}} \circ g_u \circ R_{(u,w)}.
\]

Luckily, the above expression can be further simplified because

\[
h = M_{-\frac{\pi}{3}} \circ h \circ M_{-\frac{\pi}{3}} \circ h \circ M_{-\frac{\pi}{3}},
\]

and we get

\[
\varphi_{wx} \circ \varphi_{xu} = R_{(w,u)}^{-1} \circ g_w^{-1} \circ h \circ g_u \circ R_{(u,w)} = \varphi_{wu},
\]

as desired; see Section A for detailed proofs.

It remains to find a diffeomorphism \( g_u \) from the interior of \([u', u'_{m_u - 1}, u'_0, u'_1]\) to the canonical diamond \( Q \) which satisfies the property (A).

It is natural to look for an expression of \( g_u \) in polar coordinates, and it turns out that the function

\[
g_u(\theta, r) = \left( \frac{m_u}{6}, \theta, \frac{\cos(\pi/6)}{\cos(\pi/m_u)}, r \right)
\]

does the job, in the sense that property (A) holds, and thus the corresponding \( \varphi_{wu} \) satisfies the cocycle condition.

However, we have overlooked an important point, namely that the map \( g_u \) does not map the quadrilateral \([u', u'_{m_u - 1}, u'_0, u'_1]\) onto \( Q \)! Indeed, the image of the straight edges \([u'_0, u'_1]\) and \([u'_0, u'_{m_u - 1}]\) are curved, so the image of \([u', u'_{m_u - 1}, u'_0, u'_1]\) under \( g_u \) is a diamond with curved edges; it is concave if \( m_u \geq 6 \), and convex otherwise.

In order to fix this problem, we need to modify \( \Omega_u \) or \( Q \), so that \( g_u \) is a bijection onto \( Q \). There are at least two ways to do this:
(1) Keep the canonical domain $Q$ and define $\Omega_u$ as the union of $m_u$ copies (obtained by rotations of $2k\pi/m_u$ for $k = 1, \ldots, m_u - 1$) of the inverse image of the upper triangle of $Q$ by $g_u$.

(2) Define $\Omega_u$ as the interior of the *inscribed circle* of radius $\cos(\pi/m_u)$ in the regular polygon corresponding to the old version of $\Omega_u$, and use the *canonical lens* $E$ instead of $Q$, where $E$ is the intersection of the two open disks $C$ and $D$, where $C$ is the circle of center $(0,0)$ and radius $\cos(\pi/6)$ and $D$ is the circle of center $(1,0)$ and radius $\cos(\pi/6)$; see Figure 5.8.

![Figure 5.8: The circles $C$, $D$, and the canonical lens $E$.](image)

If we choose option (1), we obtain nonconvex $p$-domains that consist of concave or convex sectors (unless $n_u = 6$). We prefer the second option because the $p$-domains are simpler and convex, which is also a crucial property for constructing parametrizations over these domains using splines or other machinery (subdivision surfaces, etc.) Therefore, in the rest of this paper, we will adopt the second option for the $p$-domains, and we will prove rigorously that the properties of gluing data are satisfied. It is worth noting that the first option is closely related to the method used by Zorin [31] to construct transition functions, but Zorin considers quadrangle meshes and his function $g_u$ rescales $r$ using an exponential. Consequently, Zorin’s functions are conformal, whereas ours are not, but our $g_u$ have the advantage of being linear in polar coordinates, and thus easier to compute (and invert).

Before presenting the details of our construction, we recall a few definitions from piecewise-linear topology (see [32]).
5.2 Simplicial surfaces

Definition 5.1. Let \( v_0, \ldots, v_d \) be any \( d + 1 \) affinely independent points in \( \mathbb{R}^n \), where \( d \) is a non-negative integer. The simplex \( \sigma \) spanned by the points \( v_0, \ldots, v_d \) is the convex hull of these points, and is denoted by

\[
[v_0, \ldots, v_d].
\]

The points \( v_0, \ldots, v_d \) are the vertices of \( \sigma \). The dimension, \( \dim(\sigma) \), of \( \sigma \) is \( d \), and \( \sigma \) is called a \( d \)-simplex.

In \( \mathbb{R}^n \), the largest number of affinely independent points is \( n + 1 \), and we have simplices of dimension 0, 1, \ldots, \( n \). A 0-simplex is a point, a 1-simplex is a line segment, a 2-simplex is a triangle, a 3-simplex is a tetrahedron, and the convex hull of any nonempty subset of vertices of a simplex is a simplex.

Definition 5.2. Let \( \sigma = [v_0, \ldots, v_d] \) be a \( d \)-simplex in \( \mathbb{R}^n \). A face of \( \sigma \) is a simplex spanned by a nonempty subset of \( \{v_0, \ldots, v_d\} \); if this subset is proper then the face is called a proper face. A face of \( \sigma \) that is a \( k \)-simplex is called a \( k \)-face. The combinatorial boundary of \( \sigma \), denoted by \( \text{bd}(\sigma) \), is the union of all proper faces of \( \sigma \). The combinatorial interior of \( \sigma \), denoted by \( \text{int}(\sigma) \), is the set \( \sigma - \text{bd}(\sigma) \).

Simplices are used as building blocks for defining simplicial complexes, which are the most general objects we can build from simplices. Simplicial complexes can be constructed by gluing simplices together along their common faces. A simplicial surface is a particular type of simplicial complex, which is made up of vertices, edges, and triangles. More formally, we have the following definition:

Definition 5.3. A simplicial complex \( \mathcal{K} \) in \( \mathbb{R}^n \) is a finite collection of simplices in \( \mathbb{R}^n \) such that

1. if a simplex is in \( \mathcal{K} \), then all its faces are in \( \mathcal{K} \);
2. if \( \sigma, \tau \in \mathcal{K} \) are simplices such that \( \sigma \cap \tau \neq \emptyset \), then \( \sigma \cap \tau \) is a face of each \( \sigma \) and \( \tau \).

The dimension, \( \dim(\mathcal{K}) \), of \( \mathcal{K} \) is the largest dimension of a simplex in \( \mathcal{K} \), i.e., \( \dim(\mathcal{K}) = \max\{\dim(\sigma) \mid \sigma \in \mathcal{K}\} \). We refer to a \( d \)-dimensional simplicial complex as simply a \( d \)-complex. The set consisting
of the union of all points in the simplices of $\mathcal{K}$ is called the *underlying space* of $\mathcal{K}$, and it is denoted by $|\mathcal{K}|$.

Figure 5.9 shows three sets of simplices in $\mathbb{R}^2$. The set on the left is not a simplicial complex because an edge and a vertex of the (combinatorial) boundary of a 2-simplex is missing. The set in the middle contains two simplices that intersect each other but the intersection is not a face of either simplex. The set on the right is a simplicial complex, as it satisfies conditions 1 and 2 of Definition 5.3.

![Figure 5.9: Collections of simplices in $\mathbb{R}^2$. Only the rightmost one is a simplicial complex.](image)

**Definition 5.4.** Let $\mathcal{K}$ be a simplicial complex in $\mathbb{R}^n$. Then, for any simplex $\sigma$ in $\mathcal{K}$, we define the sets

$$\text{st}(\sigma, \mathcal{K}) = \{\tau \in \mathcal{K} \mid \exists \eta \in \mathcal{K} \text{ such that } \sigma \text{ is a face of } \eta \text{ and } \tau \text{ is a face of } \eta\}$$

and

$$\text{lk}(\sigma, \mathcal{K}) = \{\tau \in \mathcal{K} \mid \tau \text{ is in } \text{st}(\sigma, \mathcal{K}) \text{ and } \tau \text{ and } \sigma \text{ have no face in common}\},$$

called the *star* and the *link* of $\sigma$ in $\mathcal{K}$, respectively. Note that the set $\text{st}(\sigma, \mathcal{K})$ consists of $\sigma$, all simplices of $\mathcal{K}$ that have $\sigma$ as a face, and all simplices of $\mathcal{K}$ that are faces of some simplex that has $\sigma$ as a face. In turn, the set $\text{lk}(\sigma, \mathcal{K})$ consists of all simplices in $\text{st}(\sigma, \mathcal{K})$ which do not contain $\sigma$ as a face. Moreover, both sets $\text{st}(\sigma, \mathcal{K})$ and $\text{st}(\sigma, \mathcal{K})$ are simplicial complexes, and $\text{st}(\sigma, \mathcal{K})$ is always nonempty.

Figure 5.10 illustrates the sets $\text{st}(\sigma, \mathcal{K})$ and $\text{lk}(\sigma, \mathcal{K})$ from Definition 5.4.

**Definition 5.5.** A 2-complex $\mathcal{K}$ in $\mathbb{R}^n$ is called a *simplicial surface* if every 1-simplex of $\mathcal{K}$ is the face of precisely two simplices of $\mathcal{K}$, and the underlying space of the link of each 0-simplex of $\mathcal{K}$ is
homeomorphic to the unit circle, $S^1 = \{x \in \mathbb{R}^2 \mid \|x\| = 1\}$. The underlying space of a simplicial surface is called the *underlying surface* of the simplicial surface, and it is actually a topological surface in $\mathbb{R}^n$.

Figure 5.10: A simplicial complex (left). The star of vertex $v$ (middle). The link of vertex $v$ (right).

Figure 5.11 illustrates Definition 5.5. The combinatorial boundary of a 3-simplex (i.e. a tetrahedron) is a simplicial surface (see the set on the left of Figure 5.11). But, the 2-complex, $K$, consisting of the union of the combinatorial boundaries of the two tetrahedra meeting at a vertex, $v$, is not (see the set on the right of Figure 5.11). The reason is that the link of $v$ in $K$ is not homeomorphic to $S^1$.

Figure 5.11: A simplicial surface (left), and a 2-complex that is not a simplicial surface (right).

**Definition 5.6.** Let $\mathcal{K}$ be a simplicial complex in $\mathbb{R}^n$. For each integer $i$, with $0 \leq i \leq \dim(\mathcal{K})$, we define $\mathcal{K}^{(i)}$ to be the simplicial complex consisting of all $j$-simplices of $\mathcal{K}$ with $0 \leq j \leq i$. Moreover, if $\mathcal{L}$ is a simplicial complex in $\mathbb{R}^m$, then a map $f : \mathcal{K}^{(0)} \rightarrow \mathcal{L}^{(0)}$ is called a *simplicial map* if whenever $[v_0, \ldots, v_d]$ is a simplex in $\mathcal{K}$, then $[f(v_0), \ldots, f(v_d)]$ is a simplex in $\mathcal{L}$. A simplicial map
is a simplicial isomorphism if it is a bijective map, and if its inverse is also a simplicial map. Finally, if there exists a simplicial isomorphism from \( K \) to \( L \), then we say that \( K \) and \( L \) are simplicially isomorphic.

Now, let \( K \) be any given simplicial surface in \( \mathbb{R}^3 \). Our goal is to define a set of gluing data from \( K \), say \( G = ( (\Omega_i)_{i \in I}, (\Omega_{ij})_{(i,j) \in I \times I}, (\varphi_{ji})_{(i,j) \in K} ) \).

In the following sections, we describe how each set, \( (\Omega_i)_{i \in I}, (\Omega_{ij})_{(i,j) \in I \times I}, \) and \( (\varphi_{ji})_{(i,j) \in K} \), of \( G \) is built.

### 5.3 Gluing data

In this section, we build the collections \( (\Omega_i)_{i \in I}, (\Omega_{ij})_{(i,j) \in I \times I}, \) and \( (\varphi_{ji})_{(i,j) \in K} \) of the set of gluing data, \( G \), based on the idea informally presented in Section 5.1.

Roughly speaking, each \( p \)-domain, \( \Omega_i \), in \( (\Omega_i)_{i \in I} \) is the interior of a circle in \( \mathbb{R}^2 \), while each gluing domain, \( \Omega_{ij} \), in \( (\Omega_{ij})_{(i,j) \in I \times I} \) is defined by means of two abstractions, namely, a \( P \)-polygon and its canonical triangulation, together with a composition of bijective maps. From now on, we assume that the degree of every vertex \( v \) in \( K \) (i.e., the number of edges of \( K \) having \( v \) as a 0-face) is at least 3.

Let

\[ I = \{ v \mid v \text{ is a vertex of } K \} . \]

**Definition 5.7.** For every \( v \in I \), the \( p \)-domain \( \Omega_v \) is the set

\[ \Omega_v = \left\{ (x, y) \in \mathbb{R}^2 \mid x^2 + y^2 < \left( \cos \left( \frac{\pi}{m_v} \right) \right)^2 \right\}, \]

where \( m_v \) is the degree of vertex \( v \).

Note that \( \Omega_v \) is simply the interior of a circle of radius \( \cos(\pi/m_v) \) centered at the origin of \( \mathbb{R}^2 \).

For any two \( u, w \in I \), we assume that \( \Omega_u \) and \( \Omega_w \) belong to distinct “copies” of \( \mathbb{R}^2 \). This assumption ensures that \( \Omega_u \cap \Omega_w = \emptyset \), so that condition (1) of Definition 3.1 holds. To build gluing
domains and transition maps, we need the notions of $P$-polygon and canonical triangulation. We also need to define the transition function $\varphi_{wu}$, which is the composition of two rotations around the origin, an analytic map, a Polar to Cartesian coordinate conversion map (and its inverse), and a rotation of angle $\pi$ (a double reflection).

**Definition 5.8.** For each vertex $v$ of $\mathcal{K}$, the $P$-polygon, $P_v$, associated with $v$ is the regular polygon in $\mathbb{R}^2$ with vertices $v'_0, \ldots, v'_{m_v-1}$, where $m_v$ is the degree of $v$ in $\mathcal{K}$, and such that the coordinates of $v'_i$ are

\[
\left(\cos\left(\frac{2\pi \cdot i}{m_v}\right), \sin\left(\frac{2\pi \cdot i}{m_v}\right)\right), \quad \text{for each } i \in \{0, \ldots, m_v - 1\}.
\]

Moreover, we can define the canonical triangulation, $T_v$, of $P_v$ as the triangulation of $P_v$ obtained by adding the vertex $v' = (0, 0)$ to it, as well as $m_v$ diagonals, each of which connects $v'$ to a vertex $v'_i$ of $P_v$.

Figure 5.12 illustrates Definition 5.8.

![Figure 5.12: A $P$-polygon (left) and its canonical triangulation (right).](image)

We assume that $P_v$ resides in the copy of $\mathbb{R}^2$ that contains the $p$-domain $\Omega_v$. As a result, the $p$-domain $\Omega_v$ is the interior, $\text{int}(C_v)$, of the circle, $C_v$, inscribed in the $P$-polygon, $P_v$, i.e., $\Omega_v = \text{int}(C_v)$.

Let $v$ be a vertex in $\mathcal{K}$ of degree $m_v$. Since $\mathcal{K}$ is a simplicial surface, the link, $\text{lk}(v, \mathcal{K})$, of $v$ in $\mathcal{K}$ is homeomorphic to $S^1$. So, $\text{lk}(v, \mathcal{K})$ is a simple, closed polygonal chain in $\mathbb{R}^3$. Let $v_0, \ldots, v_{m_v-1}$ be any enumeration of the vertices of $\text{lk}(v, \mathcal{K})$ such that $[v_i, v_{i+1}]$ is an edge of $\text{lk}(v, \mathcal{K})$, for each $i \in \{0, \ldots, m_v - 1\}$, where the index $i$ is considered congruent modulo $m_v$ (unless stated otherwise).
Definition 5.9. Given $\text{st}(v, \mathcal{K})$ and the canonical triangulation, $T_v$, of $P_v$, we define the map

$$s_v : \text{st}(v, \mathcal{K})^{(0)} \to T_v^{(0)}$$

such that

$$s_v(v) = v' \quad \text{and} \quad s_v(v_i) = v'_i,$$

for every $i \in \{0, \ldots, m_v - 1\}$. So, for any $x, y, z \in \text{st}(v, \mathcal{K})$, we have that $[s_v(x), s_v(y)]$ is an edge of $T_v$ if and only if $[x, y]$ is an edge of $\text{st}(v, \mathcal{K})$, and $[s_v(x), s_v(y), s_v(z)]$ is a triangle of $T_v$ if and only if $[x, y, z]$ is a triangle of $\text{st}(v, \mathcal{K})$. Thus, the map $s_v$ is a simplicial isomorphism, and $\text{st}(v, \mathcal{K})$ and $T_v$ are isomorphic. We can extend the bijection $s_v$ to mapping triangles in $\text{st}(v, \mathcal{K})$ onto triangles in $T_v$. In particular, if $\sigma = [v, v_i, v_{i+1}]$ is in $\text{st}(v, \mathcal{K})$ then $s_v(\sigma) = [v', s_v(v_i), s_v(v_{i+1})]$ is its “image” in $T_v$.

The conversion from Cartesian to polar coordinates and back is defined as follows.

Definition 5.10. Let

$$\Pi : \mathbb{R}^2 - \{(0, 0)\} \to (-\pi, \pi] \times \mathbb{R}_+$$

be the map that converts Cartesian to polar coordinates which is given by

$$\Pi(p) = \Pi((x, y)) = (\theta, r),$$

for every $p \in \mathbb{R} - \{(0, 0)\}$, where $\theta \in (-\pi, \pi]$ is the angle uniquely determined by

$$\cos \left(\frac{x}{r}\right) \quad \text{and} \quad \sin \left(\frac{y}{r}\right),$$

and $r \in \mathbb{R}_+$ is the length, with

$$r = \sqrt{x^2 + y^2}.$$

Function $\Pi$ is bijective and its inverse,

$$\Pi^{-1} : (-\pi, \pi] \times \mathbb{R}_+ \to \mathbb{R}^2 - \{(0, 0)\},$$

is given by

$$\Pi^{-1}((\theta, r)) = (r \cdot \cos(\theta), r \cdot \sin(\theta)).$$

Both $\Pi$ and $\Pi^{-1}$ are $C^\infty$ functions. We use $\Pi$ and $\Pi^{-1}$ to define a map associated with each vertex of $\mathcal{K}$:
The function $g_v$ maps $\Omega_u$ onto the circle of center $(0,0)$ and radius $\cos(\pi/6)$ and is the key to our construction, as explained in Section 5.1.

**Definition 5.11.** For each vertex $v$ in $I$, let

$$g_v : \mathbb{R}^2 - \{(0,0)\} \rightarrow \mathbb{R}^2 - \{(0,0)\}$$

be given by

$$g_v(p) = \Pi^{-1} \circ f_v \circ \Pi(p)$$

for every $p \in \mathbb{R}^2 - \{(0,0)\}$, where $f_v : (-\pi, \pi] \times \mathbb{R}_+ \rightarrow (-\pi, \pi] \times \mathbb{R}_+$ is given by

$$f_v((\theta, r)) = \left(\frac{m_v}{6} \cdot \theta, \frac{\cos(\pi/6)}{\cos(\pi/m_v)} \cdot r\right),$$

$(\theta, r)$ are the polar coordinates of $p$ and $m_v$ is the degree of vertex $v$ in $K$.

In the context of our construction, function $g_v$ has the following interpretation (refer to Figure 5.13): it maps the circular sector, $A$, of the circle $C_v$ inscribed in $P_v$, onto the circular sector, $B$, of the circle of radius $\cos(\pi/6)$ and centers at $(0,0)$, where $A$ consists of $(0,0)$ and all points with polar coordinates $(\theta, r) \in [-2\pi/m_v, 2\pi/m_v] \times (0, \cos(\pi/m_v)]$, and $B$ consists of $(0,0)$ and all points with polar coordinates $(\beta, s) \in [-\pi/3, \pi/3] \times (0, \cos(\pi/6)]$. Note that $A$ is contained in the quadrilateral given by the vertices $v', s_v(v_{m_v-1}), s_v(v_0)$, and $s_v(v_1)$ of $T_v$. We call $B$ the canonical sector.

The function $g_v$ is bijective and its inverse,

$$g_v^{-1} : \mathbb{R}^2 - \{(0,0)\} \rightarrow \mathbb{R}^2 - \{(0,0)\},$$

is given by

$$g_v^{-1}(q) = \Pi^{-1} \circ f_v^{-1} \circ \Pi(q)$$

for every $q \in \mathbb{R}^2 - \{(0,0)\}$, where $f_v^{-1} : (-\pi, \pi] \times \mathbb{R}_+ \rightarrow (-\pi, \pi] \times \mathbb{R}_+$ is given by

$$f_v^{-1}((\beta, s)) = \left(\frac{6}{m_v} \cdot \beta, \frac{\cos(\pi/m_v)}{\cos(\pi/6)} \cdot s\right),$$

$(\beta, s)$ are the polar coordinates of $q$ and $m_v$ is the degree of vertex $v$ in $K$. Since $f_v$ is clearly $C^\infty$, so is $g_v$.

We also need the rotation $h$ introduced in Section 5.1.
Definition 5.12. Let 

\[ h : \mathbb{R}^2 \to \mathbb{R}^2 \]

be the function given by 

\[ h(p) = h((x, y)) = (1 - x, -y) , \]

for every point \( p \in \mathbb{R}^2 \) with Cartesian coordinates \((x, y)\).

The function \( h \) is the rotation of center \((1/2, 0)\) and angle \( \pi \). It is a “double” reflection: \( p = (x, y) \) is reflected over the line \( x = 1/2 \) and then over the line \( y = 0 \);

Our transition maps are composite functions involving \( \Pi, g_v, h \), rotations, and their inverses. Their domains and ranges are more easily defined through an abstraction named the canonical lens.

More specifically, let \( u \) and \( w \) be any two vertices of \( K \) such that \([u, w]\) is an edge of \( K \), and as in Section 5.1, let \( R_{(u,w)} \) denote the rotation around \((0, 0)\) that takes the edge \([s_u(u) = u', s_u(w)]\) onto the edge \([u', u'_0]\) of \( T_u \).

Now, observe that \( g_u \circ R_{(u,w)} \) maps \( \Omega_u - \{(0, 0)\} \) onto the set \( \text{int}(C) - \{(0, 0)\} \), where \( C \) is the circle of radius \( \cos(\pi/6) \) and center \((0, 0)\), as illustrated by Figure 5.14. In turn, function \( h \) maps \( \text{int}(C) - \{(0, 0)\} \) onto the set \( \text{int}(D) - \{(1, 0)\} \), where \( D \) is the circle of radius \( \cos(\pi/6) \) and center \((1, 0)\). Finally, the composite function \( R_{(w,u)}^{-1} \circ g_w^{-1} \) maps \( \text{int}(C) - \{(0, 0)\} \) onto \( \Omega_w - \{(0, 0)\} \). So, only the points in the set \( \{(0, 0)\} \cap (\text{int}(D) - \{(1, 0)\}) \) are mapped by \( R_{(w,u)}^{-1} \circ g_w^{-1} \) to \( \Omega_w - \{(0, 0)\} \).

The set

\[ E = \text{int}(C) \cap \text{int}(D) \]

is called the canonical lens. This set is contained in the quadrilateral, \( Q \), given by the vertices with coordinates \((0, 0), (1/2, -\sqrt{3}/2), (1, 0), \) and \((1/2, \sqrt{3}/2)\). It is worth noticing that the set \( \Omega_w - \{(0, 0)\} \) is the image of the set \( \text{int}(C) - \{(0, 0)\} \) by \( R_{(w,u)}^{-1} \circ g_w^{-1} \) rather than the image of the set \( \text{int}(D) - \{(0, 0)\} \). Using the above notion of canonical lens, we define a key function of our construction.

Definition 5.13. For any two vertices \( u, w \) of \( I \) such that \([u, w]\) is an edge of \( K \), we define the function

\[ g_{(u, w)} : G_{uw} \to G_{wu} \]
Figure 5.13: The action of $g_v$ upon a point $p \in C_v$.

Figure 5.14: The circles $C$ and $D$, the canonical lens $E$, and the quadrilateral $Q$ (drawn with dotted line).
as
\[ g_{(u, w)}(p) = R_{(w, u)}^{-1} \circ g_w^{-1} \circ h \circ g_u \circ R_{(u, w)}(p) \]
for every point \( p \in G_{uw} \), where \( G_{uw} = R_{(w, u)}^{-1} \circ g_w^{-1}(E) \), \( G_{wu} = R_{(u, w)}^{-1} \circ g_w^{-1}(E) \), and \( E \) is the canonical lens.

Figure 5.15 shows the action of \( g_{(u, w)} \) upon a point \( p \in G_{uw} \), with \( G_{uw} = R_{(u, w)}^{-1} \circ g_u^{-1}(E) \).

Suppose that \([u, w, v]\) and \([u, w, z]\) are the two triangles of \( K \) sharing the edge \([u, w]\), where \( v \) and \( z \) are vertices of \( K \), with \( v \neq z \). Let \( Q_u \) be the quadrilateral given by the vertices \( s_u(u) = u' \), \( s_u(v) \), \( s_u(w) \), and \( s_u(z) \). Then, the composite function \( g_u \circ R_{(u, w)} \) maps the intersection \( Q_u \cap (\Omega_u - \{(0, 0)\}) \) onto the intersection set \( Q \cap (\text{int}(C) - \{(0, 0)\}) \). In turn, function \( h \) maps \( Q \cap (\text{int}(C) - \{(0, 0)\}) \) onto \( Q \cap (\text{int}(D) - \{(0, 0)\}) \). From the definition of \( h \), the points in the upper (resp. lower) half of \( Q \) are mapped to the lower (resp. upper) half of \( Q \). Next, the composite function \( R_{(w, u)}^{-1} \circ g_w^{-1} \) maps the set \( Q \cap (\text{int}(C) - \{(0, 0)\}) \) onto the set \( Q_w \cap (\Omega_w - \{(0, 0)\}) \), where \( Q_w \) is the quadrilateral given by the vertices \( s_w(w) = w' \), \( s_w(z) \), \( s_w(u) \), and \( s_w(v) \). However, since only the points of \( Q \cap (\text{int}(C) - \{(0, 0)\}) \) belonging to the canonical lens \( E \) are mapped to \( Q_w \cap (\Omega_w - \{(0, 0)\}) \) by \( R_{(w, u)}^{-1} \circ g_w^{-1} \), and since \( E \subseteq (Q \cap \text{int}(C) - \{(0, 0)\}) \), only the points of \( Q_u \cap (\Omega_u - \{(0, 0)\}) \) in the subset \( G_{uw} = R_{(w, u)}^{-1} \circ g_u^{-1}(E) \) of \( Q_u \cap (\Omega_u - \{(0, 0)\}) \) are mapped to \( Q_w \cap (\Omega_w - \{(0, 0)\}) \) by function \( g_{(u, w)} \).

Observe that \( g_{(u, w)} \) is bijective. Its inverse, \( g_{(u, w)}^{-1} : G_{wu} \rightarrow G_{uw} \), is given by
\[ g_{(u, w)}^{-1}(q) = R_{(u, w)}^{-1} \circ g_u^{-1} \circ h \circ g_w \circ R_{(w, u)}(q) , \]
for every \( q \in G_{wu} \). As we shall prove, \( g_{(u, w)} \) is \( C^\infty \), \( g_{(u, w)}(G_{uw}) \) is non-empty and open in \( \mathbb{R}^2 \), and \( g_{(u, w)}^{-1}(p) = g_{(w, u)}(p) \), for every \( p \in g_{(w, u)}(G_{wu}) \). Finally, \( g_{(u, w)} \) plays a crucial role in the following two definitions:

**Definition 5.14.** For any two vertices \( u, w \in I \), the **gluing domain** \( \Omega_{uw} \) is defined as
\[ \Omega_{uw} = \begin{cases} \Omega_u & \text{if } u = w, \\ G_{uw} & \text{if } [u, w] \text{ is an edge of } K, \text{ where } G_{uw} = R_{(w, u)}^{-1} \circ g_u^{-1}(E), \text{ and} \\ \emptyset & \text{otherwise.} \end{cases} \]

As we shall see in Appendix A, Definition 5.14 satisfies condition 2 of Definition 3.1. In addition, observe that the requirement \( \Omega_{uu} = \Omega_u \), for all \( u \in I \), is true by definition. So, we are left to prove
Figure 5.15: The action of \( g(u,w) \) upon a point \( p \in G_{uw} \), with \( G_{uw} = R_{(u,w)}^{-1} \circ g_u^{-1}(E) \).
that the set $\Omega_{uw}$ is open in $\mathbb{R}^2$ and $\Omega_{uw} \neq \emptyset$ if and only if $\Omega_{wu} \neq \emptyset$, for every $(u, w) \in I \times I$, with $u \neq w$.

Transition maps are bijective functions between non-empty gluing domains defined as follows:

**Definition 5.15.** Let $K$ be the index set,

$$K = \{(u, w) \in I \times I \mid \Omega_{uw} \neq \emptyset\}.$$

Then, for any pair $(u, w) \in K$, the transition map,

$$\varphi_{wu} : \Omega_{uw} \to \Omega_{wu},$$

is such that, for every $p \in \Omega_{uw}$, we let

$$\varphi_{wu}(p) = \begin{cases} p & \text{if } u = w, \\ g_{(u,w)}(p) & \text{otherwise.} \end{cases}$$

Figure 5.16 illustrates Definition 5.15.

The functions $g_{(u,w)}$ possess the two properties (A) and (B) described in Section 5.1, that play a crucial role in proving that the transition maps introduced in Definition 5.15 satisfy conditions 3 and 4 of Definition 3.1. The details are given in Appendix A but we state and prove these two properties right now.

**Proposition 5.1.** The maps $g_u$ satisfy the following properties:

(A) For all $q \in g_u(\Omega_u)$, we have

$$(g_u \circ M_{-\frac{2\pi}{m}} \circ g_u^{-1})(q) = M_{-\frac{\pi}{3}}(q) \quad \text{and} \quad (g_u \circ M_{\frac{2\pi}{m}} \circ g_u^{-1})(q) = M_{\frac{\pi}{3}}(q),$$

where $M_{-\frac{\pi}{3}}$ (resp. $M_{\frac{\pi}{3}}$) is a rotation by $-\frac{\pi}{3}$ (resp. $\frac{\pi}{3}$) around the origin, and $M_{\frac{2\pi}{m}}$ (resp. $M_{-\frac{2\pi}{m}}$) is a rotation by $\frac{2\pi}{m_u}$ (resp. $\frac{2\pi}{m_u}$) around the origin, with $m_u$ the degree of vertex $u$ in $K$.

(B) If $s_u(w)$ precedes $s_u(v)$ in a counterclockwise enumeration of the vertices of $K$, then

$$(g_u \circ R_{(u,w)})(p) = (M_{\frac{\pi}{3}} \circ g_u \circ R_{(u,v)})(p)$$

for all $p \in \Omega_{uw}$. 

46
Proof. (A) If \((\alpha, s)\) and \((\beta, t)\) are the polar coordinates of \(q\) and \(g_u \circ M_{\frac{2\pi}{m_u}} \circ g_u^{-1}(q)\), respectively, then the definition of \(g_u\) tells us that
\[
\beta = \frac{m_u}{6} \cdot \left( -\frac{2\pi}{m_u} + \frac{6}{m_u} \cdot \alpha \right) = -\frac{\pi}{3} + \alpha
\]
and
\[
t = \frac{\cos(\pi/6)}{\cos(\pi/m_u)} \cdot \frac{\cos(\pi/m_u)}{\cos(\pi/6)} \cdot s = s
\]
so
\[
(g_u \circ M_{\frac{2\pi}{m_u}} \circ g_u^{-1})(q) = M_{-\frac{\pi}{3}}(q),
\]
as claimed. A similar argument with \(-2\pi/m_u\) replaced by \(2\pi/m_u\) proves the second identity.

(B) Since \(s_u(w)\) precedes \(s_u(v)\) in a counterclockwise enumeration, we have
\[
R_{(u,w)} \circ R_{(u,v)}^{-1} = M_{\frac{2\pi}{m_u}}.
\]
Consequently
\[
(g_u \circ R_{(u,w)})(p) = (g_u \circ M_{\frac{2\pi}{m_u}} \circ R_{(u,v)})(p),
\]
but using (A), we have
\[
g_u \circ M_{\frac{2\pi}{m_u}} = M_{\frac{\pi}{3}} \circ g_u
\]
on \(\Omega_u\), so we get
\[
(g_u \circ R_{(u,w)})(p) = (M_{\frac{\pi}{3}} \circ g_u \circ R_{(u,v)})(p)
\]
for all \(p \in \Omega_{uw}\), as claimed. \(\square\)
Note that the proof of (B) shows that (B) actually follows from (A), and the fundamental fact that $R_{(u,w)} \circ R_{(u,v)}^{-1} = M_{\frac{\pi}{3\mu}}$ (when $s_u(w)$ precedes $s_u(v)$ in a counterclockwise enumeration of the vertices of $T_u$). Also, observe that condition 3a, $\varphi_{uu} = \text{id}_{\Omega_u}$, for all $u \in I$, is true by definition. So, we are left to prove conditions 3b and 3c (the cocycle condition). Condition 3b is proved using Proposition 5.1. Once condition 3b has been proved, it is easy to prove that condition 3c holds using Proposition 5.1 (see Lemma A.8). We also show in Appendix A that the Hausdorff condition (condition 4) holds.

We developed a computer program for building sets of gluing data from simplicial surfaces\footnote{http://www.dimap.ufrn.br/~mfsiqueira/Marcelo_Siqueiras_Web_Spot/Software.html}. Our program is based on the construction described above, and it also allows us to define a Parametric Pseudo-Surface (PPS) from the gluing data. The computational aspects of this program are detailed in [18]. In particular, we describe in [18] how to define and compute a family of parametrizations, $(\theta_v)_{v \in I}$, from a simplicial surface, $K$, so that $(G, \theta_v)_{v \in I}$ is a parametric pseudo-surface (PPS) in $\mathbb{R}^3$. Figure 5.17-6.2 show approximations to the images of three PPSs generated by the aforementioned program.

Figure 5.17: (a) The boundary of a tetrahedron. (b) Approximation to a PPS defined from (a).
6 Conclusions

We gave a novel and constructive definition of gluing data, and proved that a universal manifold can always be built from a set of gluing data. Our definition fixed a flaw in the definition of the pioneering work of Grimm and Hughes [12], and provided a necessary and sufficient condition for building Hausdorff spaces from sets of gluing data. To demonstrate the applicability of our definition, we showed how to construct sets of gluing data from simplicial surfaces, and then proved the correctness of our construction. Although this construction is limited to simplicial surfaces, our definition of sets of gluing data is not. In principle, sets of gluing data can be built from other objects.

![A star-shaped simplicial surface.](a)

![Approximation to a PPS defined from (a).](b)

Figure 6.1: (a) A star-shaped simplicial surface. (b) Approximation to a PPS defined from (a).

We also introduced a class of spaces called parametric pseudo-manifolds (or PPM’s for short), which under certain conditions are manifolds embedded in $\mathbb{R}^n$, for some positive integer $n$. PPM’s can be naturally defined from sets of gluing data, and they are powerful representations for manifolds arising in several graphics and engineering applications [1, 2, 3, 4, 5, 6, 7, 9]. We have already used PPM’s for building $C^\infty$-surfaces in $\mathbb{R}^3$ that approximate simplicial surfaces [18]. Unlike other approaches for constructing surfaces, such as the stitching paradigm [1] or subdivision surfaces [33],
sets of gluing data and PPM’s allowed us to build $C^k$ surfaces, for a large integer $k$ or even $k = \infty$, with ease.

![Triangulated surface](image1.png) ![Smoothed surface](image2.png)

**Figure 6.2:** (a) A simplicial surface. (b) Approximation to a PPS defined from (a).

As future work is concerned, we intend to create an analogous definition of sets of gluing data for building manifolds with boundary. This definition would definitely increase the range of applications for manifold-based constructions. A manifold-based construction for surfaces with boundary in $\mathbb{R}^3$ already exists [34], but it is not based on any definition of sets of gluing data for manifolds with boundary. We are also developing a construction for building gluing data from point sets in $\mathbb{R}^n$. This sort of construction benefits from existing techniques for manifold learning [11] and point set surfaces [35].

The main obstacle in developing constructions for gluing data is the cocycle condition (see Definition 3.1). The reason is that it does not seem easy to find transition maps that satisfy the cocycle condition and are still simple to invert and evaluate. For instance, we were unable to find polynomial transition maps for the construction described in Section 5. The reader may also wonder why the $p$-domains are not the interior of the $P$-polygons (but the interior of the circle inscribed in the $P$-polygon). The reason is that we were also unable to find diffeomorphisms defined on
the interior of the $P$-polygons. In this respect, we showed that if a map satisfies condition (A) of Proposition 5.1, then it satisfies the cocycle condition. However, we do not know whether condition (A) is a necessary condition. We also do not know whether the diffeomorphism given by the Schwarz-Christoffel formula satisfies the cocycle condition. We leave these as open problems. It is interesting to remark that affine maps between triangles of the canonical triangulations of the $P$-polygons satisfy the cocycle condition, but do not yield $C^k$-functions, for $k \geq 1$, along common edges of adjacent triangles. In turn, projective maps between quadrilaterals formed from two adjacent triangles are $C^\infty$, but do not satisfy the cocycle condition (see [36] for details).

A Construction correctness

We now prove that the construction described in Section 5.3 is correct. This amounts to showing that the triple $\mathcal{G}$ defined in Section 5.3 is a set of gluing data in the sense of Definition 3.1. Formally, we have:

**Theorem A.1.** Given any given simplicial surface, $\mathcal{K}$, in $\mathbb{R}^3$, the triple

$$ \mathcal{G} = ((\Omega_v)_{v \in I}, (\Omega_{uw})_{(u,w) \in I \times I}, (\varphi_{uw})_{(u,w) \in \mathcal{K}}), $$

where

- $(\Omega_v)_{v \in I}$ is any set of $p$-domains for $\mathcal{K}$,
- $(\Omega_{uw})_{(u,w) \in I \times I}$ is the set of gluing domains for $\mathcal{K}$ with respect to $(\Omega_v)_{v \in I}$,
- $(\varphi_{uw})_{(u,w) \in \mathcal{K}}$ is the set of transition maps defined by Definition 5.15, and
• $K = \{(u, w) \in I \times I \mid \Omega_{uw} \neq \emptyset\}$,

is a set of gluing data according to Definition 3.1.

Our proof of Theorem A.1 relies on several straightforward claims, which are stated and proved in the remaining of this Appendix. We start by showing that Definition 5.14 satisfies condition 2 of Definition 3.1.

**Proposition A.2.** Let $\Omega_u$ and $\Omega_w$ be any two $p$-domains of $(\Omega_v)_{v \in I}$. Then, $\Omega_{uw} \neq \emptyset$ if and only if $\Omega_{wu} \neq \emptyset$.

**Proof.** If $u = w$, our claim is trivially true. So, let us assume that $u \neq w$. Now, suppose that $\Omega_{uw} \neq \emptyset$. So, from Definition 5.14, we must have that $[u, w]$ is an edge of $K$. Otherwise, $\Omega_{uw}$ would be empty. By Definition 5.14 again, the fact that $[u, w]$ is an edge of $K$ implies that $\Omega_{uw}$ is equal to $G_{uw}$, which in turn is equal to $R_{(w,u)}^{-1} \circ g_w^{-1}(E)$. Since both $R_{(w,u)}^{-1}$ and $g_w^{-1}$ are bijective, and since $E \neq \emptyset$, we get that $\Omega_{wu} \neq \emptyset$. Conversely, if $\Omega_{wu} \neq \emptyset$ then we can use the same argument to conclude that $\Omega_{uw} \neq \emptyset$. $\square$

**Proposition A.3.** Let $\Omega_u$ and $\Omega_w$ be any two $p$-domains of $(\Omega_v)_{v \in I}$. Then, the gluing domain $\Omega_{uw}$ is an open set of $\mathbb{R}^2$.

**Proof.** If $u = w$ then our claim is trivially true, as $\Omega_{uu} = \Omega_u$ and $\Omega_u$ is open in $\mathbb{R}^2$ (by definition). So, assume that $u \neq w$. If $\Omega_{uw} = \emptyset$ then our claim is trivially true. So, assume that $\Omega_{uw} \neq \emptyset$.

From Definition 5.14, if $\Omega_{uw} \neq \emptyset$ then $[u, w]$ is an edge of $K$, which means that $\Omega_{uw} = G_{uw} = R_{(u,w)}^{-1} \circ g_u^{-1}(E)$. So, $\Omega_{uw}$ is the inverse image, under the function $g_u \circ R_{(u,w)}$, of an open set, $E$, of $\mathbb{R}^2$. But, since $g_u \circ R_{(u,w)}$ is continuous and $E$ is open in $\mathbb{R}^2$, we must have that $\Omega_{uw}$ is also open in $\mathbb{R}^2$. $\square$

The following propositions state several useful properties of $g_{(u,w)}$:

**Proposition A.4.** For any two $u, w \in I$ such that $[u, w]$ is an edge of $K$, function $g_{(u,w)}$ is $C^\infty$.

**Proof.** By definition,

$$g_{(u,w)}(p) = R_{(w,u)}^{-1} \circ g_w^{-1} \circ h \circ g_u \circ R_{(u,w)}(p),$$

for every $p \in \Omega_u - \{(0,0)\}$. Since $R_{(w,u)}^{-1}$, $g_w^{-1}$, $h$, $g_u$, and $R_{(u,w)}$ are all $C^\infty$ functions, so is $g_{(u,w)}$. $\square$
Proposition A.5. For any two vertices, \( u \) and \( w \), of \( K \) such that \([u, w]\) is an edge of \( K \), and for every \( p \) in \( G_{wu} \),
\[
g_{(u,w)}^{-1}(p) = g_{(w,u)}(p).
\]

Proof. By definition, we have that \( g_{(u,w)}(p) = R_{(w,u)}^{-1} \circ g_{w}^{-1} \circ h \circ g_{u} \circ R_{(u,w)}(p) \), for every \( p \in G_{(u,w)} \).

But, the composite function \( g_{u} \circ R_{(u,w)} \) maps \( G_{(u,w)} \) onto the set \( E \), where \( E \) is the canonical lens.

In turn, \( h(E) = E \), and the composite function \( R_{(w,u)}^{-1} \circ g_{w}^{-1} \) maps \( E \) onto \( G_{wu} \). So, \( g_{(u,w)} \) maps \( G_{uw} \) onto \( G_{wu} \). Using the same argument, we can conclude that \( g_{(w,u)} \) maps \( G_{wu} \) onto \( G_{uw} \). Furthermore, we get
\[
g_{(u,w)}^{-1}(p) = (R_{(w,u)}^{-1} \circ g_{w}^{-1} \circ h \circ g_{u} \circ R_{(u,w)})^{-1}(p) = R_{(u,w)}^{-1} \circ g_{u}^{-1} \circ h \circ g_{w} \circ R_{(w,u)}(p) = g_{(w,u)}(p),
\]
for every \( p \in G_{wu} \).

We now show that the transition maps (see Definition 5.15) satisfy conditions 3 and 4 of Definition 3.1. Although conditions 3a and 3b follow from condition 3c, the exposition of our proof of condition 3c assumes that conditions 3a and 3b are true, so we first show that conditions 3a and 3b hold.

Proposition A.6. For any \((u, w) \in K\), we have that \( \varphi_{wu}(p) = \varphi_{uw}^{-1}(p) \), for all \( p \in \Omega_{uw} \).

Proof. From Definition 5.15, if \( u = w \) then \( \varphi_{wu} = \varphi_{uw} = \text{id}_{\Omega_{u}} \). Otherwise, we have \( \varphi_{wu} = g_{(u,w)} \) and \( \varphi_{uw} = g_{(w,u)} \).

In the former case, our claim is trivially true. In the latter case, Proposition A.5 states that \( g_{(u,w)}^{-1}(p) = g_{(w,u)}(p) \), for every \( p \in \Omega_{uw} \). Since \( \varphi_{uw}(p) = g_{(w,u)}(p) = g_{(u,w)}^{-1}(p) = \varphi_{uw}^{-1}(p) \), our claim follows.

Our proof of condition 3c relies on a property of function \( g_{u} \), called rotational symmetry, as follows:

Proposition A.7. Let \([u, w, z]\) be any triangle of \( K \). If \( s_{u}(z) \) precedes \( s_{u}(w) \) in a counterclockwise traversal of the vertices of \( P_{u} \), then
\[
M_{\pi/3} \circ g_{u} \circ R_{(u,w)}(\Omega_{uw}) = g_{u} \circ R_{(u,w)}(\Omega_{uz}) \quad \text{and} \quad M_{\pi/3} \circ g_{u} \circ R_{(u,z)}(\Omega_{uz}) = g_{u} \circ R_{(u,z)}(\Omega_{uw}).
\]

Furthermore,
\[
\Omega_{uz} = M_{\frac{2\pi}{m_{u}}} \left( \Omega_{uw} \right) \quad \text{and} \quad \Omega_{uw} = M_{\frac{2\pi}{m_{u}}} \left( \Omega_{uz} \right).
\]
Proof. From Definition 5.14, we have that
\[ \Omega_{uw} = G_{uw} \quad \text{and} \quad \Omega_{uz} = G_{uz}. \]

Since \( g_u \circ R_{(u,w)} \) and \( g_u \circ R_{(u,z)} \) are bijective, we also have that
\[ g_u \circ R_{(u,w)}(G_{uw} \cap G_{uz}) = g_u \circ R_{(u,w)}(G_{uw}) \cap g_u \circ R_{(u,w)}(G_{uz}) \]
and
\[ g_u \circ R_{(u,z)}(G_{uw} \cap G_{uz}) = g_u \circ R_{(u,z)}(G_{uw}) \cap g_u \circ R_{(u,z)}(G_{uz}). \]

But,
\[ g_u \circ R_{(u,w)}(G_{uw}) = E = g_u \circ R_{(u,z)}(G_{uz}), \]
where \( C \) is the circle of radius \( \cos(\pi/6) \) and center \((0,0)\). Furthermore, we also have that
\[ g_u \circ R_{(u,w)}(G_{uz}) = \int(C) \cap \int(F), \]
where we used the property that \( R_{(u,w)} \circ R_{(u,z)}^{-1} \circ M_{\frac{2u}{m_u}} \circ g_u^{-1} \circ h \circ g_z \circ R_{(z,u)}(G_{zu}) = M_{-\frac{\pi}{3}} \circ h \circ g_z \circ R_{(z,u)}(G_{zu}), \]
\[ = M_{-\frac{\pi}{3}}(E) = \int(C) \cap \int(F), \]
where we used the property that \( R_{(u,w)} \circ R_{(u,z)}^{-1} = M_{\frac{2u}{m_u}} \) and Proposition 5.1 (A) to claim that
\[ g_u \circ M_{\frac{2u}{m_u}} \circ g_u^{-1} = M_{-\frac{\pi}{3}}, \]
where \( F \) is the circle of radius \( \cos(\pi/6) \) and center \((1/2, \sqrt{3}/2)\) (see Figure A.1).

So,
\[ g_u \circ R_{(u,w)}(G_{uw}) = \int(C) \cap \int(D) \]
and
\[ g_u \circ R_{(u,w)}(G_{uz}) = \int(C) \cap \int(F). \]

But, since
\[ M_{-\frac{\pi}{3}}(\int(D)) = \int(F), \]
we get
\[ M_{-\pi/3} \circ g_u \circ R_{(u,w)}(G_{uw}) = g_u \circ R_{(u,w)}(G_{uz}). \]
To show that $M_{π/3} \circ g_u \circ R_{(u,z)}(Ω_{uz}) = g_u \circ R_{(u,z)}(Ω_{uw})$, we can proceed as before, but noting that

$$R_{(u,z)} \circ R_{(u,w)}^{-1} = M_{2π \over μ_u} \quad \text{and} \quad g_u \circ M_{2π \over μ_u} \circ g_u^{-1} = M_{π \over 3}.$$ 

To prove the second claim, note that

$$M_{2π \over μ_u}(Ω_{uw}) = M_{2π \over μ_u}(G_{uw})$$

$$= M_{2π \over μ_u}(g_{(w,u)}(G_{wu}))$$

$$= M_{2π \over μ_u} \circ R_{(u,w)}^{-1} \circ g_u^{-1} \circ h \circ g_w \circ R_{(w,u)}(G_{wu})$$

$$= R_{(u,z)}^{-1} \circ g_w^{-1}(E)$$

$$= Ω_{uz}.$$ 

To show that $M_{2π \over μ_u}(Ω_{uz}) = Ω_{uw}$ holds, we can proceed as before, but noting that $M_{2π \over μ_u} \circ R_{(u,z)}^{-1} = R_{(u,w)}^{-1}$.

We can now prove the first implication of Condition 3c of Definition 3.1.

**Lemma A.8.** Let $Ω_u$, $Ω_w$, and $Ω_x$ be any three $p$-domains in $(Ω_v)_{v \in I}$. If the intersection $Ω_{ux} \cap Ω_{wx}$ is nonempty, then

$$φ_{ux}^{-1}(Ω_{ux} \cap Ω_{wx}) = Ω_{ux} \cap Ω_{uw}.$$ 

**Proof.** We distinguish three cases: (a) $u = w = x$, (b) $u = w$ and $u \neq x$, or $u = x$ and $u \neq w$, or $w = x$ and $u \neq w$, and (c) $u \neq w$, $u \neq x$, and $w \neq x$. Case (a) is trivial, as $Ω_{ux} \cap Ω_{wx} = Ω_x$, and thus $φ_{ux}^{-1}(Ω_{ux} \cap Ω_{wx}) = id_{Ω_x}(Ω_x) = Ω_x = Ω_{uw}$. Case (b) is also trivial. If $u = w$ and $u \neq x$ then $Ω_{ux} \cap Ω_{ux} = Ω_{ux}$, and thus $φ_{ux}^{-1}(Ω_{ux} \cap Ω_{ux}) = φ_{ux}^{-1}(Ω_{ux}) = Ω_{ux}$. In turn, if $u = x$ and $u \neq w$ then $Ω_{ux} \cap Ω_{wx} = Ω_{xx} \cap Ω_{wx} = Ω_x \cap Ω_{wx} = Ω_{xx}$, and thus $φ_{ux}^{-1}(Ω_{ux} \cap Ω_{wx}) = id_{Ω_x}(Ω_{xx}) = Ω_{xx} = Ω_{uw}$. Finally, if $w = x$ and $u \neq w$ then $Ω_{ux} \cap Ω_{uw} = Ω_{uw} \cap Ω_{uw} = Ω_{uw} \cap Ω_{uw}$, and thus $φ_{ux}^{-1}(Ω_{ux} \cap Ω_{uw}) = φ_{ux}^{-1}(Ω_{ux}) = Ω_{ux} = Ω_{uw}$. So, consider case (c): $u \neq w$, $u \neq x$, and $w \neq x$.

Assume that the edges $[u, w]$, $[u, x]$, and $[w, x]$ of $K$ are shared by the triangles $[u, w, x]$ and $[u, w, z]$, $[u, w, x]$ and $[u, x, y]$, and $[u, w, x]$ and $[v, x, w]$ of $K$, respectively. We will first show the following:

$$g_{(u,x)}^{-1}(Ω_{ux} \cap Ω_{wx}) = Ω_{ux} \cap Ω_{uw}.$$ 

58
In fact, since \( g^{-1}_{(u,x)} \) is bijective,
\[
g^{-1}_{(u,x)}(\Omega_{ux} \cap \Omega_{uw}) = g^{-1}_{(u,x)}(\Omega_{ux}) \cap g^{-1}_{(u,x)}(\Omega_{uw}) = g(x,u)(\Omega_{ux}) \cap g(x,u)(\Omega_{uw}) = \Omega_{ux} \cap g(x,u)(\Omega_{uw}) .
\]
By definition,
\[
g(x,u)(\Omega_{uw}) = R^{-1}_{(u,x)} \circ g^{-1}_{u} \circ h \circ g_x \circ R(x,u)(\Omega_{uw}) .
\]
From Proposition A.7, we have that
\[
R^{-1}_{(u,x)} \circ g^{-1}_{u} \circ h \circ g_x \circ R(x,u)(\Omega_{uw}) = R^{-1}_{(u,x)} \circ g^{-1}_{u} \circ h \circ M_{\pi/3} \circ g_x \circ R(x,u)(\Omega_{ux}) ,
\]
where \( M_{\pi/3} \) is a rotation by \( \pi/3 \) around the origin. By construction, the composite function \( g_x \circ R(x,u) \) maps \( \Omega_{ux} \) onto the canonical lens, \( E = \text{int}(C) \cap \text{int}(D) \), where \( C \) is the circle of radius \( \cos(\pi/6) \) and center \( (0,0) \) and \( D \) is the circle of radius \( \cos(\pi/6) \) and center \( (1,0) \). So, we get that
\[
h \circ M_{\pi/3} \circ g_x \circ R(x,u)(\Omega_{ux})
\]
is the set
\[
\text{int}(D) \cap \text{int}(G),
\]
where \( G \) is the circle of radius \( \cos(\pi/6) \) and center \( (1/2, -\sqrt{3}/2) \). But, only the points of the above set that also in \( \text{int}(C) - \{(0,0)\} \) are mapped by \( R^{-1}_{(u,x)} \circ g^{-1}_{u} \) to \( \Omega_{u} \). So, \( g(x,u)(\Omega_{uw}) \cap \Omega_{u} \) is the image of
\[
\text{int}(C) \cap \text{int}(D) \cap \text{int}(G)
\]
under \( R^{-1}_{(u,x)} \circ g^{-1}_{u} \) (see Figure A.2).

Now, we claim that the image of \( \Omega_{ux} \cap \Omega_{uw} \) under \( g_u \circ R(u,x) \) is also equal to
\[
\text{int}(C) \cap \text{int}(D) \cap \text{int}(G) .
\]
In fact,
\[
g_u \circ R(u,x)(\Omega_{ux} \cap \Omega_{uw}) = g_u \circ R(u,x)(\Omega_{ux}) \cap g_u \circ R(u,x)(\Omega_{uw}) .
\]
By definition,
\[
g_u \circ R(u,x)(\Omega_{ux}) = E = \text{int}(C) \cap \text{int}(D) .
\]
In turn, from Proposition A.7, we know that \( g_u \circ R(u,x)(\Omega_{uw}) = M_{\pi/3} \circ g_u \circ R(u,x)(\Omega_{uw}) \). So,
\[
g_u \circ R(u,x)(\Omega_{uw}) = M_{\pi/3}(E) = \text{int}(C) \cap \text{int}(G) ,
\]
59
and hence
\[ g_u \circ R_{(u,x)}(\Omega_{ux} \cap \Omega_{uw}) = \text{int}(C) \cap \text{int}(D) \cap \text{int}(G). \]

So,
\[
\Omega_{ux} \cap \Omega_{uw} = g_{(x,u)}(\Omega_{xw}) \cap \Omega_u \\
= g_{(x,u)}(\Omega_{xw}) \cap \Omega_{ux} \\
= g_{(x,u)}(\Omega_{xw}) \cap g_{(x,u)}(\Omega_{xu}) \\
= g_{(x,u)}(\Omega_{xw} \cap \Omega_{xu}) \\
= g_{(u,x)}^{-1}(\Omega_{xw} \cap \Omega_{xu}).
\]

Since \( \varphi_{xu}^{-1}(p) = g_{(u,x)}^{-1}(p) \), for every \( p \in \Omega_{xu} \), we get \( \varphi_{xu}^{-1}(\Omega_{xu} \cap \Omega_{xw}) = \Omega_{ux} \cap \Omega_{uw} \), and hence our claim is true.

The second and last implication of condition 3c of Definition 3.1 also holds:

**Lemma A.9.** Let \( \Omega_u, \Omega_w, \) and \( \Omega_x \) be any three \( p \)-domains in \((\Omega_v)_{v \in I}\). If \( \Omega_{xu} \cap \Omega_{xw} \neq \emptyset \), then
\[ \varphi_{wu}(p) = \varphi_{wx} \circ \varphi_{xu}(p), \]
for all \( p \in \varphi_{xu}^{-1}(\Omega_{xu} \cap \Omega_{xw}) = \Omega_{ux} \cap \Omega_{uw}. \)

**Proof.** From Lemma A.8, we know that \( \varphi_{wu} \) is well-defined for all points in \( \varphi_{xu}^{-1}(\Omega_{xu} \cap \Omega_{xw}) = \Omega_{ux} \cap \Omega_{uw} \). So, we are left to show that \( \varphi_{wu} = \varphi_{wx} \circ \varphi_{xu} \). Assume that \( u, w, \) and \( x \) are all distinct; otherwise, if two of them are equal or all of them are the same, our claim would be reduced to condition 3b of Definition 3.1, which has been proved. Since the indices \( u, w, \) and \( x \) are assumed to be pairwise distinct, Definition 5.15 tells us that \( \varphi_{wu} = g_{(u,w)}, \varphi_{wx} = g_{(x,w)}, \) and \( \varphi_{xu} = g_{(u,x)} \). So, we need to prove that
\[ g_{(u,w)}(p) = g_{(x,w)} \circ g_{(u,x)}(p), \]
for all \( p \in g_{(u,x)}^{-1}(\Omega_{xu} \cap \Omega_{xw}) = \Omega_{ux} \cap \Omega_{uw}. \)

From Definition 5.13, we know that
\[
\begin{align*}
g_{(u,w)} &= R_{(w,u)}^{-1} \circ g_w^{-1} \circ h \circ g_u \circ R_{(u,w)}, \\
g_{(u,x)} &= R_{(x,u)}^{-1} \circ g_x^{-1} \circ h \circ g_u \circ R_{(u,x)},
\end{align*}
\]
Figure A.1: The sets $g_u \circ R_{(u,w)}(\Omega_{uw})$ and $g_u \circ R_{(u,w)}(\Omega_{uz})$.

Figure A.2: The sets $h \circ M_{\pi/3} \circ g_x \circ R_{(u,x)}(\Omega_{xu})$ and $h \circ g_x \circ R_{(u,x)}(\Omega_{xu})$. 
Next, from Proposition \( A.7 \) on \( g \) we know that

\[
g(x, w) = R_{(w, x)}^{-1} \circ g_w^{-1} \circ h \circ g_x \circ R_{(x, w)}. \tag{3}
\]

So,

\[
g(x, w) \circ g(u, x) = R_{(w, x)}^{-1} \circ g_w^{-1} \circ h \circ g_x \circ R_{(x, w)} \circ R_{(x, u)}^{-1} \circ g_x^{-1} \circ h \circ g_u \circ R_{(u, x)}. \tag{4}
\]

To show that the right side of Eq. (4) is equal to the right side of Eq. (1), we invoke Proposition A.7. Consider the triangles \([s_u(u), s_u(w), s_u(x)], [s_w(u), s_w(w), s_w(x)],\) and \([s_x(u), s_x(w), s_x(x)]\) of \( T_u, T_w, \) and \( T_x, \) respectively (see Figure A.3). Without loss of generality, suppose that \( s_u(x) \) follows \( s_u(w) \) in a counterclockwise traversal of the vertices of \( P_u. \) This means that \( s_w(u) \) follows \( s_w(x) \) in a counterclockwise traversal of the vertices of \( P_w, \) and that \( s_x(w) \) follows \( s_x(u) \) in a counterclockwise traversal of the vertices of \( P_x. \) Now, let \( p \) be a point in \( g_{(u, x)}^{-1}(\Omega_{ux} \cap \Omega_{uw}). \) From Lemma A.8, we know that

\[
g_{(u, x)}^{-1}(\Omega_{ux} \cap \Omega_{uw}) = \Omega_{ux} \cap \Omega_{uw}.
\]

We now show how to simplify the expression

\[
g(x, w) \circ g(u, x) = R_{(w, x)}^{-1} \circ g_w^{-1} \circ h \circ g_x \circ R_{(x, w)} \circ R_{(x, u)}^{-1} \circ g_x^{-1} \circ h \circ g_u \circ R_{(u, x)}.
\]

First, note that

\[
R_{(x, w)} \circ R_{(x, u)}^{-1} = M_{-\frac{2\pi}{m_x}},
\]

as \( s_x(w) \) follows \( s_x(u) \) in a counterclockwise traversal of \( P_x, \) where \( m_x \) is the degree of \( x. \) We get

\[
g(x, w) \circ g(u, x) = R_{(w, x)}^{-1} \circ g_w^{-1} \circ h \circ g_x \circ M_{-\frac{2\pi}{m_x}} \circ g_x^{-1} \circ h \circ g_u \circ R_{(u, x)}.
\]

By Proposition 5.1 (A) we have

\[
g_x \circ M_{-\frac{2\pi}{m_x}} \circ g_x^{-1} = M_{-\frac{\pi}{\frac{m_x}{2}}}
\]

on \( g_u(\Omega_u), \) so we get

\[
R_{(w, x)}^{-1} \circ g_w^{-1} \circ h \circ g_x \circ M_{-\frac{2\pi}{m_x}} \circ g_x^{-1} \circ h \circ g_u \circ R_{(u, x)} = R_{(w, x)}^{-1} \circ g_w^{-1} \circ h \circ M_{-\frac{\pi}{\frac{m_x}{2}}} \circ h \circ g_u \circ R_{(u, x)}. \tag{5}
\]

Next, from Proposition A.7, we know that

\[
g_u \circ R_{(u, x)}(\Omega_{uw}) = M_{-\frac{\pi}{\frac{m_x}{2}}} \circ g_u \circ R_{(u, w)}(\Omega_{uw}),
\]
Figure A.3: Illustration of the cocycle condition.
Since \( p \in g_{(u,x)}^{-1}(\Omega_{xu} \cap \Omega_{xw}) \), we can conclude from Proposition 5.1 (B) that

\[
g_u \circ R_{(u,x)}(p) = M_{-\frac{\pi}{3}} \circ g_u \circ R_{(u,w)}(p),
\]

(6)

For the same reason, we also know that

\[
g_w \circ R_{(w,x)}(q) = M_{\frac{\pi}{3}} \circ g_w \circ R_{(w,u)}(q),
\]

for every \( q \in g_{(w,x)}^{-1}(\Omega_{xu} \cap \Omega_{xw}) = \Omega_{ux} \cap \Omega_{wx} \). So, by Proposition 5.1 (B)

\[
R_{(w,x)}^{-1} \circ g_{(w,x)}^{-1}(t) = R_{(w,u)}^{-1} \circ g_{(w,u)}^{-1}(t),
\]

(7)

for every \( t \), where \( t = g_w \circ R_{(w,x)}(q) \) for some \( q \in g_{(w,x)}^{-1}(\Omega_{xu} \cap \Omega_{xw}) \).

Substituting the right-hand side of the identities in Eq. (6) and Eq. (7) with their left side into Eq. (5), we get

\[
R_{(w,x)}^{-1} \circ g_{w}^{-1} \circ h \circ M_{-\frac{\pi}{3}} \circ h \circ g_u \circ R_{(u,x)} = R_{(w,u)}^{-1} \circ g_{w}^{-1} \circ M_{-\frac{\pi}{3}} \circ h \circ M_{-\frac{\pi}{3}} \circ h \circ M_{-\frac{\pi}{3}} \circ g_u \circ R_{(u,w)}.
\]

(8)

This means that

\[
g(x,w) \circ g(u,x) = R_{(w,u)}^{-1} \circ g_{w}^{-1} \circ M_{-\frac{\pi}{3}} \circ h \circ M_{-\frac{\pi}{3}} \circ h \circ M_{-\frac{\pi}{3}} \circ g_u \circ R_{(u,w)}.
\]

(9)

Now, the above expression can be further simplified because

\[
h = M_{-\frac{\pi}{3}} \circ h \circ M_{-\frac{\pi}{3}} \circ h \circ M_{-\frac{\pi}{3}}.
\]

This is because it is easily checked that \( h \circ M_{-\frac{\pi}{3}} \) is the rotation of center \((\sqrt{3}/4, 1/2)\) and angle \(\pi - \pi/3 = 2\pi/3\), which implies that

\[
h \circ M_{-\frac{\pi}{3}} \circ h \circ M_{-\frac{\pi}{3}} \circ h \circ M_{-\frac{\pi}{3}} = \text{id}_{\mathbb{R}^2},
\]

and since \( h \circ h = \text{id}_{\mathbb{R}^2} \), we have \( h = M_{-\frac{\pi}{3}} \circ h \circ M_{-\frac{\pi}{3}} \circ h \circ M_{-\frac{\pi}{3}} \), as claimed. So, we have that

\[
g(x,w) \circ g(u,x)(p) = R_{(w,u)}^{-1} \circ g_{w}^{-1} \circ h \circ g_u \circ R_{(u,w)}(p) = g(u,w)(p),
\]

(10)

for every \( p \in g_{(u,x)}^{-1}(\Omega_{xu} \cap \Omega_{xw}) \).

Finally, we show that condition 4 of Definition 3.1 also holds:
Lemma A.10. Let \((u, w)\) be any pair in \(K\), with \(u \neq w\). Then, for every \(x \in \partial(\Omega_{uw}) \cap \Omega_u\) and every \(y \in \partial(\Omega_{wu}) \cap \Omega_w\), there are open balls, \(V_x\) and \(V_y\), centered at \(x\) and \(y\), such that no point of \(V_y \cap \Omega_{wu}\) is the image of any point \(V_x \cap \Omega_{uw}\) under \(\varphi_{wu}\).

Proof. By definition, each gluing domain, \(\Omega_{uw}\), is the image by \(R_{(u, w)}^{-1} \circ g_u^{-1}\) of the canonical lens, \(E\), given by

\[\text{int}(C) \cap \text{int}(D),\]

where \(C\) and \(D\) are the circles of radius \(\cos(\pi/6)\) and centers \((0, 0)\) and \((1, 0)\), respectively. Furthermore, the gluing domain \(\Omega_{uw}\) is also a lens-shaped set whose boundary, \(\partial(\Omega_{uw})\), is the image by \(R_{(u, w)}^{-1} \circ g_u^{-1}\) of the boundary, \(\partial(E)\), of \(E\). We can view \(\partial(\Omega_{uw})\) as the union of two open and simple curve segments, \(C_{ue}\) and \(C_{ui}\), such that \(C_{ue}\) belongs to \(\partial(\Omega_{uw})\) and the interior, \(\text{int}(C_{ui})\), of \(C_{ui}\) belongs to the interior of \(\Omega_u\) (see Figure A.4). In addition, the pairs of endpoints of both curves, \(C_{ue}\) and \(C_{ui}\), are the same, and each pair is the image by \(R_{(u, w)}^{-1} \circ g_u^{-1}\) of the two intersection points of the boundaries, \(\partial(C)\) and \(\partial(D)\), of \(C\) and \(D\). Similarly, the boundary, \(\partial(\Omega_{wu})\), of the gluing domain, \(\Omega_{wu}\), can be viewed as the union of two curves, \(C_{we}\) and \(C_{wi}\), such that \(C_{we}\) belongs to \(\partial(\Omega_{wu})\) and the interior, \(\text{int}(C_{wi})\), of \(C_{wi}\) belongs to the interior of \(\Omega_w\). In addition, the pairs of endpoints of both curves, \(C_{we}\) and \(C_{wi}\), are the same, and each pair is the image by \(R_{(w, u)}^{-1} \circ g_w^{-1}\) of the two intersection points of the boundaries, \(\partial(C)\) and \(\partial(D)\), of \(C\) and \(D\), as also shown in Figure A.4.

\[\text{int}(C_{ui}) = \partial(\Omega_{uw}) \cap \Omega_u \quad \text{and} \quad \text{int}(C_{wi}) = \partial(\Omega_{wu}) \cap \Omega_w.\]
Note also that
\[ g(u,w)(C_{u_i}) = C_{w_e} \quad \text{and} \quad g(w,u)(C_{w_i}) = C_{u_e}. \]
Indeed,
\[ g(u,w)(C_{u_i}) = R^{-1}_{(w,u)} \circ g^{-1}_w \circ h \circ g_u \circ R_{(u,w)}(C_{u_i}). \]
By construction, we know that \( g_u \circ R_{(u,w)}(C_{u_i}) \in \partial(C) \), which implies that \( h \circ g_u \circ R_{(u,w)}(C_{u_i}) \in \partial(D) \). So,
\[ R^{-1}_{(w,u)} \circ g^{-1}_w \circ h \circ g_u \circ R_{(u,w)}(C_{u_i}) = C_{w_e}. \]
Finally, let \( x \) be any point in \( \partial(\Omega_{uw}) \cap \Omega_u \). Since \( \text{int}(C_{u_i}) = \partial(\Omega_{uw}) \cap \Omega_u \), we have that \( x \in \text{int}(C_{u_i}) \). From our discussion above, we also have that if \( p = g_{(u,w)}(x) \) then \( p \in \text{int}(C_{w_e}) \). Since \( \text{int}(C_{w_e}) \cap \text{int}(C_{u_i}) = \emptyset \), there exists an open ball, \( V_p \), centered at \( p \) such that \( V_p \cap \text{int}(C_{w_i}) = \emptyset \), which follows from the fact that \( \mathbb{R}^2 \) is a Hausdorff space. Since \( \text{int}(C_{u_i}) = \partial(\Omega_{uw}) \cap \Omega_w \), we get that
\[ V_p \cap (\partial(\Omega_{uw}) \cap \Omega_w) = \emptyset. \]
In turn, for any point \( y \in \partial(\Omega_{uw}) \cap \Omega_w \), there exists an open ball, \( V_y \), such that \( V_y \cap V_p = \emptyset \) (see Figure A.5). This also follows from the fact that \( \mathbb{R}^2 \) is a Hausdorff space. So, define \( V_x \) to be any open ball centered at \( x \) such that \( V_x \subseteq g^{-1}_{(u,w)}(V_p) \). By construction, we know that \( g_{(u,w)}(V_x) \cap V_y = \emptyset \). To conclude that our claim is true, it suffices to notice that \( g_{(u,w)}(V_x \cap \Omega_{uw}) \subseteq \Omega_w \) and that \( \varphi_{wu} = g_{(u,w)} \) for every point in \( \Omega_{uw} \), which implies that \( \varphi_{wu}(V_x \cap \Omega_{uw}) \cap (V_y \cap \Omega_{wu}) = \emptyset \). So, our claim follows.

We can now prove Theorem A.1:
Proof. Our claim follows immediately from the facts that our construction yields $p$-domains, gluing domains, and transition functions that satisfy conditions 1 through 4 of Definition 5.15. Indeed, the $p$-domains are open sets in $\mathbb{R}^2$. Proposition A.2 and Proposition A.3 ensure that the gluing domains satisfy condition 2 of Definition 5.15, while Proposition A.6, Lemma A.8, and Lemma A.9 ensure that the transition functions satisfy condition 3. Finally, Lemma A.10 states that condition 4 holds. \qed
