Behaving as Expected: Public Information and Fairness Norms

Abstract

What is considered to be fair depends on context-dependent expectations. Using a modified version of the Ultimatum Game, we demonstrate that both fair behavior and perceptions of fairness depend upon beliefs about what one *ought* to do in a situation—that is, upon *normative expectations*. We manipulate such expectations by creating informational asymmetries about the offer choices available to the Proposer, and find that behavior varies accordingly. Proposers and Responders show a remarkable degree of agreement in their beliefs about which choices are considered fair. We discuss how these results fit into a theory of social norms.

Abstract

What is considered to be fair depends on context. Using a modified version of the Ultimatum Game, we demonstrate that both fair behavior and perceptions of fairness depend upon beliefs about what one *ought* to do in a situation – that is, upon *normative expectations*. We manipulate such expectations by creating informational asymmetries about the offer choices available to the Proposer, and find that behavior varies accordingly. Proposers and Responders show a remarkable degree of agreement in their beliefs about which choices are considered fair. We discuss how these results fit into a theory of social norms.

Keywords: game theory, fairness, social norms, normative expectations.

Behaving as Expected: Public Information and Fairness Norms

Introduction

Social norms are often invoked as explanations of pro-social behavior. Since norms are ubiquitous in society, it is important to be able to assess under which conditions individuals will be motivated to follow them, and to distinguish norm-motivated behavior from generic social preferences. To accomplish these goals, we need an operational definition of norms that allows us to make testable predictions about when norms will be followed, as well as to distinguishing norms from other concepts such as conventions or personal values. In what follows we adopt a definition of norms that is grounded upon individuals' preferences and expectations (Bicchieri, 2006, p.11).

For a social norm to exist and be followed, three conditions must be present. First, it is necessary that the individuals involved *believe* it exists and know the class of situations to which the norm pertains. This condition implies that individuals must be aware they are in a situation in which a particular norm applies, since lack of awareness may lead to non-compliance. We thus hypothesize that making a norm salient will lead, *ceteris paribus*, to more compliance (Cialdini et al., 1990). The second condition is that individuals must have a *conditional preference* for following the norm. Specifically, an individual will prefer to obey a given norm if she (a) expects other people to comply with it (empirical expectations) and (b) believes that other people expect her to obey the norm and may sanction transgressions (normative expectations). The third condition is the presence of empirical and normative expectations. It follows that an individual may not obey a norm she knows applies to a given situation if she fails to have the right kind of expectations. Transgressions may occur because one observes non-compliance, or

alternatively normative expectations are absent, or they are present but one can violate them without being observed.

The conditional preference condition distinguishes social norms from personal values. In the latter case, one usually has an unconditional preference for following a certain rule, as expectations about others' compliance play little or no role in one's decision. Having a conditional preference for conformity also implies that one might follow a norm in the presence of the relevant expectations, but disregard it in their absence. We thus hypothesize that manipulation of expectations will produce major shifts in norm-abiding behavior. To test this hypothesis, we focused on a simple version of the Ultimatum game, in which one of the parties proposes a division of a fixed amount of money to another party who can then accept or reject the offer. If the offer is rejected, both parties get nothing. Experimental results show that participants' modal and mean offers are 40 to 50% of the total amount, and offers below 20% are rejected about half of the time (Camerer, 2003). These results are generally interpreted as showing that subjects have a preference for fairness (Fehr & Schmidt, 1999).

Our hypothesis instead is that subjects have a conditional preference for following fairness norms, and manipulation of expectations will lead to significantly different behavior among the same subjects in different conditions. These results cannot be explained by a fairness preference hypothesis, since the material consequences are the same across conditions, and the only difference between conditions is the level of information (and thus the expectations) of players. Furthermore, even if we were to modify the fairness preference hypothesis by making preferences conditional, it would

remain to be explained under which conditions preferences would change. The theory of norms we adopt provides such a testable explanation.

To show that “fair” behavior is dictated by norms that are conditionally followed, we manipulated both salience and expectations. In the salience treatment, we asked Proposers which of the options they thought Responders believed to be fair, thus focusing them on Responders’ normative expectations. Our hypothesis was that making a fairness norm more salient would induce greater fairness on the part of Proposers. In both the salience and non-salience conditions, we asked Responders which of the Proposers’ choice options they believed to be fair. The goal of this assessment was twofold. First, we wanted to check whether there was agreement in Responders’ normative expectations. Agreement strongly indicates the presence of a shared norm of fairness. Second, we wanted to assess the agreement of Responders’ normative expectations with Proposers’ beliefs about them. It is significant that Proposers’ answers (in the salience conditions) agreed with the overall Responders’ answers, a fact that further indicates the presence of a shared norm.

What counts as fair may vary by context, and in a given context more than one fairness criterion might apply. Equity and equality considerations may coexist, and randomization is often perceived as a fair allocation mechanism, as when we use a lottery to allocate transplant organs. In our experiment, we added a choice option that randomized with equal probability between an equal and a very unequal share. Remarkably, a majority of Responders found this option fair, a finding also reflected in the Proposers’ beliefs about Responders’ assessments. Adding this option allowed us to check for *norm manipulation* (Bicchieri, 2007). That is, when a norm can have several

interpretations, individuals will tend to adopt the one most favorable to them. This form of self-serving bias has been studied in the context of equity vs. equality interpretations of fairness (Frey & Bohnet 1995; Hoffman & Spitzer 1985), and we show that we can elicit the same bias with a suitable random option, provided this choice option is common knowledge among participants.

To manipulate expectations, we changed the information conditions in three versions of the same division problem. We expected a change in normative expectations to affect Proposers' choices. We also predicted the occurrence of *norm evasion* (Bicchieri, 2007): whenever it was possible for Proposers to defy normative expectations without Responders' knowledge, the proportion of unfair offers would be significantly higher. Due to the conditional nature of norm compliance, the more ambiguous the choice situation, the higher will be the proportion of individuals that flaunt the norm, since their behavior cannot be clearly interpreted as intentional, and thus no sanctioning is expected to occur.

Our paper is a contribution to a field that may be labeled *behavioral ethics*. It should be seen as a subfield of behavioral decision theory, taking into account social and psychological considerations in an attempt to understand pro-social, "moral" choices. In this regard, we explore whether and why a pro-social norm will be followed, trying to gain insights about decision-making and motivation that are useful for further developing a behavioral account of moral choices.

Method

Participants

One hundred and six college-age subjects participated in our study across 11 experimental sessions. Advertisements specified that participants would earn 5 USD in addition to an amount that would depend on decisions made during the experiment.

Game Paradigm

Our experimental design employed a variant of the Ultimatum Game (Guth et al., 1982), in which one participant, the *Proposer*, provisionally received a sum of 10 USD – provided by the experimenter – and then proposed a division of that money with a *Responder*. The Responder subsequently decided to accept or reject the proposal. If the Responder accepted, both players received the amounts specified in the proposal. If the Responder rejected, both players received \$0. The Proposer chose from one of the following options:

(5,5) - to propose \$5 for the Proposer, and \$5 for the Responder;

(8,2) - to propose \$8 for the Proposer, and \$2 for the Responder; and

Coin - to let the outcome of a fair coin flip determine the proposal: heads corresponded to (5,5), and tails to (8,2).

Procedure

Upon their arrival, participants randomly drew ID codes labeled A1, A2, ..., An and B1, B2, ..., Bn, where n is twice the number of participants in the session, and proceeded either to Room A or B based on their codes. We distributed and read aloud a set of instructions, which explained the following:

- Based on random assignment, the participants in Room A were Proposers, and those in Room B were Responders.

- Participants would play three games,[†] each with a different person in the other room.
- By means of a public randomization device, we would select two of the three games at the end of the study to determine participants' cash payments.
- For each game, we would post on the blackboard the Proposer-Responder pairings using their ID codes, distribute instructions specific to that game, and then administer a short quiz to test their understanding of the instructions. By posting pairings publically, we maximized transparency and the likelihood that each participant would believe he or she actually was interacting with three different people in the other room.
- Subsequently, Proposers would be given a proposal form on which they would write their ID codes and choose one of the available proposals.
- After all Proposers completed their proposal forms, an assistant would take them to Room B, where the Responders would mark their decision to accept or reject the proposal.

Comment [AKC1]: This addresses Reviewer 1's Minor Comment #1.

Information

The proposal form that was used for each of the three games was determined by the information condition which we assigned to that game. Appendix B contains the proposal forms which differed slightly by information condition, as described below.

In the *full information* condition, the proposal form listed all three options: (5,5), (8,2), and coin. After Proposers completed their proposal forms, the experimenter in

[†] We described the games using the language of Hoffman et al. (1994).

Room B flipped a coin in front of the Responders in case any Proposer had marked coin on her form. On any forms on which the Proposer chose coin, the experimenter then marked (5,5) or (8,2) based on the coin flip outcome. The instructions explained this, so that prior to making their decisions, all participants understood that Responders would know if the Proposers with whom they were paired chose coin.

In the *private information* condition, the Responder did not know that coin was available to Proposers, and Proposers knew this fact. To create this informational asymmetry, we left coin out of the proposal form. The experimenter in Room A explained to Proposers that they could indicate a coin choice by leaving both (5,5) and (8,2) unmarked; subsequently, the experimenter would flip a coin in Room A, and on any such forms, mark (5,5) if the outcome was heads, and (8,2) if the outcome was tails. Thus, Proposers understood that Responders were unaware that coin was an available option.

In the *limited information* condition, both Proposers and Responders knew that coin was available, but also that Responders would not be able to infer whether the Proposer chose coin or marked one of (5,5) and (8,2) directly. Specifically, the instructions explained that Proposers could indicate a coin choice by leaving both (5,5) and (8,2) unmarked on their proposal forms. The experimenter in Room B would flip a coin and mark (5,5) or (8,2) accordingly on any such forms. Crucially, he would flip the coin behind a small screen, so that no participant could see the outcome. Thus, all participants understood that the Responder would be unable to distinguish forms on which the Proposer chose (5,5) or (8,2) directly from forms on which the Proposer chose coin.

Finally, because Proposers did not receive feedback between conditions, and to minimize participants' confusion that occurred during a pilot study, we fixed the order of the information conditions as 1) full, 2) private, and 3) limited.

Saliency

In each information condition, prior to making their choices, Responders completed a questionnaire that measured their normative expectations (see Appendix C). The questionnaire asked whether the responder found each of the three choice options fair. The questionnaire was aimed at assessing whether there was an agreement in Responders' normative expectations, an indicator of (as well as a necessary condition for) the existence of a social norm. In addition, roughly half of our experimental sessions included an incentive-based questionnaire for both Responders and Proposers, which they completed in each information condition, following the quiz but prior to making their choices (See Appendices D and E).[‡]

These questionnaires asked participants about their beliefs about the percentage of Responders who indicated (5,5), (8,2) and coin, respectively, as fair options. The questionnaires were designed to 1) make fairness norms more salient, and 2) test for an agreement between Responders' normative expectations and Proposers' beliefs about them. The other half of the sessions included no such questionnaires; they just included the first Responders' questionnaire (Appendix C). We distinguish salient sessions which included these two extra questionnaires from non-salient sessions which did not.

Design and Analyses

[‡] For Responders in the saliency condition, the second questionnaire in Appendix D was appended to the one in Appendix C.

The experiment used a 3 x 2 design, crossing three levels of a within-participant variable, information (full, private, and limited), with two levels of a between-participant variable, salience (non-salient and salient). The primary dependent variable was the Proposer's choice: (5,5), (8,2), or Coin.

We used a mixed-effects multinomial logit model to estimate choice probabilities. To determine the significance of information, salience, their interaction, and participant-level random effects, we used nested model comparisons based on the likelihood ratio test statistic (LRT). Because small cell sizes made it inadvisable to base inference about the LRT on the chi-square distribution, we generated p-values for model comparisons using the non-parametric bootstrap. Bootstrap p-values lead to more accurate inference when cell counts are sparse. For the same reason, we generated p-values for the logit coefficients using the bootstrap. Appendix A contains additional details on the [bootstrap methods we employed](#).

Deleted: To correct p-values for multiple comparisons, we used Buja & Rolke's (2007) method of calibration for simultaneous inference.

Deleted: statistical methods we employed

Hypotheses

We first hypothesized that, if there is a social norm, there must be agreement between Responders' normative expectations and Proposers' beliefs about them. We also hypothesized that choices would depend on information condition and salience. Based on the theory presented in the Introduction, we made several directional predictions by considering possible scenarios involving relevant fairness norms.

Firstly, we predicted that the proportion of coin choices would be higher in the full information condition than in the private or limited conditions. This follows because in the private information condition, there are no normative expectations for coin (as the

availability of coin is unknown to Responders), and there should therefore be very few coin choices, since an outcome of (8,2) is likely to be rejected as unfair. In the limited condition, Responders could not determine whether the Proposer chose coin. Therefore the expected utility of coin is a combination of the probability of getting (5,5) or (8,2), and the probability that (8,2) will be accepted.[§] If the Proposer assesses a probability greater than 5/8 that (8,2) will be accepted, she will choose (8,2). If the probability is less than 5/8, the Proposer will choose (5,5). Only if the probability is exactly 5/8, the Proposer will be indifferent among the three options. Therefore, Proposers who believed that less than 62.5% of Responders would accept (8,2) would choose (5,5), since the expected value of choosing (8,2) would be less than 5. Proposers who believed that more than 62.5% of Responders would accept (8,2) would choose (8,2), since the expected value of choosing (8,2) would be more than 5. In either case, there will be few or no coin choices. Finally, in the full information condition, as long as there were Proposers who thought that choosing coin was perceived to be fair by Responders, the proportion of coin choices would be positive. This is because these Proposers believe that the expected utility of choosing coin is 6.5, while the expected utilities of choosing (5,5) or (8,2) are, respectively, 5 and 0. This is an example of *norm manipulation*; i.e., participants would adopt the (allegedly shared) interpretation of fairness that would benefit them the most. Indeed, coin maximizes expected monetary payoff without violating fairness.

Secondly, we predicted that there would be more (8,2) choices in the limited than in the full or private information conditions, because some Proposers would take

[§] The expected utility of coin is equal to $\frac{1}{2}(5) + \frac{1}{2}(8)p$. p is the probability that the Responder will accept (8,2) because he believes that the Proposer is 'playing fair' and thinks coin is a fair choice. The expected utility of (5,5) is 5, and the expected utility of (8,2) is $8p$. The value of p that makes one indifferent between the three options is 5/8, or .625.

advantage of the ambiguity of their choice. Specifically, if some Proposers believed that a large enough fraction of Responders thought that choosing coin was fair and that Proposers were playing fair by choosing Coin, then these Proposers could evade the norm and maximize their monetary expected value by choosing (8,2) in the limited information condition.** Thus, the proportion of (8,2) choices should be higher in the limited information condition than in the full information condition. In the private information condition, we expected the fraction of (8,2) choices to be low for reasons discussed below.

Thirdly, we predicted that there would be more (5,5) choices in the private than in the full or limited information conditions. Previous work has indicated that the proportion of (5,5) choices is around 70% when (5,5) and (8,2) are the only available options (Falk et al., 2000). Because the private information condition is most similar to this situation, and we expected (5,5) to be almost universally considered fair, we expected similar proportions of (5,5) choices. In the full information condition, because we expected a relatively larger number of coin choices (due to norm manipulation), we expected fewer (5,5) choices. In the limited information condition, because we expected a relatively larger number of (8,2) choices (as the ambiguity of choices led to norm evasion), we expected fewer (5,5) choices.

Finally, because we expected the questionnaire in the salient condition to focus Proposers on fairness – i.e., on choosing either (5,5) or coin, and not (8,2) – we predicted that the above effects would be amplified.

Results

** That is, p must be greater than .625 for a Proposer to choose (8,2) in the limited condition.

Deleted: We summarize our predictions below. Let $\pi_{\{x, y, z\}}$ denote the proportion of choice x in information condition y and salience treatment z .
Hypotheses (1) – (6). Choice proportions follow a social norm in which (5,5) and coin are viewed as fair, but (8,2) is not, for both the control and salient conditions:
 $\pi_{\{coin, full, control\}} > \max(\pi_{\{coin, private, control\}}, \pi_{\{coin, limited, control\}})$... [1]

Choices by Information and Salience

Figure 1 shows the choice proportions for each level of Information x Salience.

As salience effects appeared to be small, we averaged across salience conditions in reporting the choice proportions below. 37.7% (20/53) of Proposers chose coin in the full information condition, compared to 11.3% (6/53) in the private condition and 5.7% (3/53) in the limited condition, consistent with our first hypothesis. Consistent with our second hypothesis, more Proposers chose (8,2) in the limited condition (58.5% [31/53]) than in the full (24.5% [13/53]) or private (37.7% [20/53]) conditions. We observed the highest frequency of (5,5) choices in the private condition (50.9% [27/53]) relative to the full (37.7% [20/53]) and limited (35.8% [19/53]) conditions, consistent with our third hypothesis.

The primarily additive effect of salience combined with differences in choice proportions across information conditions suggests the presence of both main effects, but not their interaction. Indeed, nested model comparisons (see Table 1) confirmed that a model with main effects of information and salience – but not their interaction – fit the choice data the best. Participant-level random effects were not significant for any of the models in Table 1.

Table 2 shows the estimates for the model with both main effects of information and salience. Consistent with a norm-based explanation of choices, when normative expectations for coin are either absent (in the private condition) or can be defied without consequence (in the limited condition), the predicted probabilities of (5,5) and (8,2), respectively, are considerably higher than those of coin. This is indicated by the significantly positive coefficients. On the other hand, when normative expectations for

Deleted: Table 1 shows choice percentages and choice fractions by information and salience.

coin are present and choices are transparent (in the full information condition), (5,5) is no more likely than coin ($p = .963$), whereas (8,2) is in fact less likely ($p = .038$). The substantial discrepancy between some of the maximum likelihood (ML) and bootstrap estimates of the standard error were due to right-skewed coefficients distributions; accordingly, we used percentiles of the bootstrap distribution to calculate p-values, instead of relying on the asymptotic normality of the coefficients.

Deleted: ¶

Based on the model with both main effects, we performed formal tests of our first three hypotheses using bootstrapping to generate p-values (see Appendix A). As suggested by Figure 1, the probability of coin was significantly higher in the full information condition than in the private or limited information conditions ($p < .001$, for both the salient and non-salient conditions). (8,2), additionally, was more likely to be chosen in the limited condition than in the full or private information conditions ($p < .02$, for both the salient and non-salient conditions). (5,5), however, was not more likely to be chosen in the private condition than in the other other two conditions ($p = .1$ and $p = .2$ respectively for the salient and non-salient conditions). Thus, we found support for our first two hypotheses but not for our third.

Deleted: Hypothesis Tests¶
Figure 2 shows tests of our nine a priori hypotheses (1)-(9) using differences in predicted probabilities.

Deleted: is

Deleted: higher

Deleted: for each of (5)-(6); however, these effects are only marginally significant when considering all nine tests simultaneously ($p_{adj} < .08$)

We found mixed support for our final set of hypotheses, that Proposers would be more focused on fairness in the salient condition and would therefore be more likely to choose (5,5) and coin, and less likely to choose (8,2). Respectively in the salient and non-salient conditions, there were 41 and 25 (5,5) choices ($p = .003$); 17 and 12 coin choices ($p = .2$); and 26 and 38 (8,2) choices ($p = .016$), where again we generated bootstrapped p-values using the model with both main effects. Because the interaction between salience and information was not significant (see Table 1), the norm-focusing effects

reported above were limited to across information conditions.

Normative Expectations and Beliefs about Them

Table 3 reports the normative expectations of Responders. Clearly, almost all Responders considered (5,5) to be fair in all information conditions, and a majority of them also thought that Coin was fair. This may be surprising because the expected utility of Coin is only 3.5 USD for the Responder, whereas it is 6.5 USD for the Proposer. A possible explanation is that using a random device is perceived as a fair way to choose between alternatives. Responders might have compared Coin to the temptation of (8,2) and found the Proposer who refused to choose between (5,5) and (8,2) as one making a fair choice. Alternatively, some might have thought the Proposer, because of her role, had an entitlement to a greater share, and Coin seemed a fair compromise between five dollars and eight dollars.

Figures 2-4 show participants' beliefs about Responders' normative expectations for each information condition. There is a remarkable degree of agreement between Responders' and Proposers' beliefs about the normative expectations of Responders. Moreover, a comparison of Table 3 with Figures 2-4 shows that participants' beliefs about normative expectations are in agreement with the normative expectations themselves.

Such high degree of agreement is the strongest possible indication that there is a shared norm of fairness. Not only is (5,5) universally perceived as fair, but also Coin is thought to be fair by a majority of participants. This agreement explains the tendency to choose a self-serving interpretation of fairness (norm manipulation) in the full

Deleted: The probability of (8,2) was higher in the non-salient treatment ($p_{adj} = .029$), as predicted in (9). In addition, the prediction (8), that the probability of (5,5) would be higher in the salient treatment, was significant when considered alone ($p = .0139$), but only marginally so when considered simultaneously with all nine tests ($p_{adj} < .09$). Furthermore, the probability of Coin was not significantly different by salience condition ($p_{adj} < .80$). Lastly, (5,5) was not more likely in the private conditions than in the others ($p_{adj} > .46$).¶

information condition, as well as the pattern of choices across information conditions, as we show in the following section.

Choices as a Function of Beliefs about Normative Expectations

A social norm explanation presupposes consistency between beliefs and behavior. In particular, it requires consistency between participants' beliefs about normative expectations and their subsequent choices. As we show below, the data show a high degree of consistency between beliefs and behavior.

We denote the Proposers' belief about the proportion of Responders who consider (5,5), (8,2), and coin, respectively, as being fair by $\varphi(5,5)$, $\varphi(8,2)$, and $\varphi(\text{coin})$. The distributions of these variables are summarized by Figures 2-4. To determine whether these beliefs could explain the variance in Proposer's choices, we fit a multinomial logit with information condition and the three questionnaire variables as predictors, based on a stepwise search.^{††} The signs of the coefficients for the questionnaire variables were in the appropriate directions (see Table 4). As the Proposer's belief that the Responder considered (5,5) to be fair increased, (8,2) became less likely relative to the reference choice of coin ($p = .068$). As $\varphi(\text{coin})$ increased, the odds of choosing coin over (5,5) increased as well ($p = .048$). For higher levels of $\varphi(8,2)$, coin was less likely than (8,2) ($p = .068$).

Figures 5a-b show the predicted probabilities of (8,2) choices by condition as

^{††} We used a stepwise search that minimized Akaike's information criterion (AIC), a function of the likelihood which penalizes larger models ($AIC = -2(\log\text{-likelihood}) + 2k$, where k is the number of parameters in the model that are being estimated). The scope of the model search were information, $\varphi(5,5)$, $\varphi(8,2)$, and $\varphi(\text{coin})$. When we expanded the scope to search amongst all two-way interactions as well, AIC selected a model which included $\varphi(8,2) \times \varphi(\text{coin})$ in addition to the variables in Table 4 (AIC=158.61). However, we chose to present the simpler model without this interaction term, as it did not change our substantive results, and Figures 6-7 looked the same with or without it.

Deleted: 5

functions of $\varphi(8,2)$ and $\varphi(\text{Coin})$, respectively. In the private information condition, for example, a Proposer who believes that no Responders find (8,2) to be fair (i.e., $\varphi(8,2) = 0$) has a predicted probability of .23 of choosing (8,2) -- see Figure 5a.^{††} However, a Proposer who believes that roughly 60% of Responders find (8,2) to be fair is more than twice as likely to choose (8,2), with a predicted probability of .55.

Deleted: 6a

The strong dependency of (8,2) choices on the Proposer's belief that Coin is considered to be fair in the limited information condition (see Figure 5b) is also noteworthy. A Proposer who believes that no Responders find Coin to be fair has a predicted probability of only .10 of choosing (8,2). However, a Proposer who believes that all Responders find Coin to be fair has a predicted probability of .53 of choosing Coin, a five-fold increase. This occurs because the Proposer can choose (8,2) with impunity when the Proposer's estimate of the probability that Coin is considered fair by Responders is high. If the Proposer believes that a) the Responder thinks Coin is fair and b) the Responder believes that the Proposer is playing fair by choosing Coin, then (8,2) is expected to be accepted with high probability because it will be interpreted as the unlucky outcome of a coin flip. Moreover, as Figure 5b shows, the predicted probability of (8,2) choices in the limited information condition increases with the Proposer's estimate of the probability that Coin is considered fair by Responders. Whereas the existence of more than one interpretation of fairness leads to norm manipulation (i.e., the Proposer chooses Coin instead of (5,5) in the full information condition), the presence of ambiguity leads to norm evasion (i.e., the Proposer chooses (8,2) in the limited information condition because the source of the offer is not identifiable as being

Deleted: 6b

Deleted: 6b

^{††} The other belief variables are held fixed at their median values for these predictions.

intentional or due to chance). Indeed, 76% of Proposers choose (8,2) in the limited information condition. And even when Proposers are focused on fairness in the salience condition, the proportion of (8,2) choices is relatively high.

Deleted: As Table 1 clearly shows

Finally, Figure 6 shows the predicted probability of Coin choices as a function of $\phi(\text{Coin})$ by condition. Clearly, the probability of choosing Coin increases with the Proposer's estimate of the proportion of Responders who consider Coin to be fair. As mentioned earlier, the Proposer's self-serving bias would lead to a greater frequency of Coin choices whenever it is clear that Responders know that Coin has been chosen and that they consider Coin to be fair. This can also be seen in Figure 1, where the proportion of Coin choices in the full information condition is substantially larger relative to the other information conditions.

Deleted: 7

Deleted: Table 1

Responder Behavior

Table 5 shows that Responders discriminated between intentional offers and offers that were generated by a chance mechanism. In the full information condition, no (8,2) offers resulting from a Coin choice were rejected, whereas intentional (8,2) offers were rejected 23% of the time. Responders' rejection rates of (8,2) were also sensitive to the presence of an intermediate choice. In the private information condition, in which Responders believe the only choices are (5,5) and (8,2), the rejection rate is much higher than in the full information condition (40% vs. 23%), in which Responders know that the Coin choice is available. When there is ambiguity as to the source of the choice, as in the limited information condition, the rejection rate of (8,2) was low (16.1%). This suggests that the large majority of Responders who receive an (8,2) offer in the limited

Deleted: 6

information condition believe both that it is the result of a Coin choice and that choosing Coin is fair. The large number of Proposers who choose (8,2) in the limited information condition seem to expect this low rate of rejections.

Conclusions

Having a well-defined, testable theory of social norms allows us to explain what would *prima facie* appear to be inconsistencies in individual behavior. Individuals choose to be fair on occasion, but revert to selfish behavior on others. The theory of social norms we adopt explains away these apparent inconsistencies. Compliance with a norm is conditional upon having the right kind of empirical and normative expectations. It is also important that individuals focus on the relevant norm in order for them to comply with it. The theory of we adopt (Bicchieri, 2006) predicts that making a norm salient will tend to increase compliance and, even more important, that the presence of the appropriate expectations is crucial for attaining conformity to the norm. We thus expected that manipulating expectations by changing the information available to individuals would result in large shifts in behavior.

The data we presented highlight two important phenomena connected to norm compliance. The first is norm manipulation (Bicchieri, 2007): when a norm can have several interpretations, individuals will tend to choose the interpretation that best serves their interests. This effect is evident in the choice of Coin in the full information condition. In this condition, the participants have common knowledge of the Proposer's access to the three choices of (5,5), (8,2), and Coin, as well as the Responder's ability to differentiate between an intentional unfair offer and an unfair offer resulting from a

chance event. In the full information condition, the proportion of coin choices is the same as the proportion of (5,5) choices. Moreover, this manipulation of the fairness norm is made possible by the implicit and strong agreement among the Responder's normative expectations about the fairness of Coin choices and both Proposers' and Responders' agreement about such normative expectations. As we mentioned at the outset, such an agreement is a strong indication of the presence of a shared norm.

The second phenomenon is norm evasion. Norm evasion differs from norm avoidance, in which an individual avoids a specific situation to which a norm applies. A vivid example of norm avoidance is the behavior of the Iks described by Turnbull (1972). The Iks repaired their huts in the middle of the night so as to avoid their neighbors' offers of help, as such offers had to be accepted, and that involved incurring an obligation that the beneficiary wanted to avoid. Norm evasion, on the contrary, is the deliberate, private flouting of a norm even if one knows the normative expectations of the relevant parties. For many individuals, the presence of normative expectations without the sanctioning element weakens the grip of the norm. Such expectations can be violated at no cost, as the victim will not be able to distinguish an intentional action from a chance event. Norm evasion explains Proposers' behavior in the limited information condition, in which (8,2) was the most frequent choice.

Our work introduces the field of behavioral ethics and builds on the seminal work of Guth et al. (1982) and Hoffman et al. (1994), who showed the importance of context in games requiring the division of resources. We add to that work by showing that the effect of context is mediated by the role that normative expectations and shared norms hold in explaining behavior. Secondly, our measurement of first-order (Responders'

Comment [AKC2]: This might not be the right phrasing, so should perhaps be left out.

fairness judgments) and second-order (Proposers' and Responders' beliefs about Responders' fairness judgments) beliefs is a highly useful but underused method in experiments on strategic interactions. Thirdly, our results potentially allow us to

Deleted: Another reason why our results are significant is that they

distinguish between different types of individuals. Future work will explore how a more fine-grained account of individuals' sensitivity to specific norms explains their choices, and whether there are correlations between sensitivities to different norms, such as those of cooperation, fairness, and reciprocity. Strong correlations would indicate the existence of a general disposition to follow social norms, whereas a low correlation would indicate that norm compliance is a local, norm-specific phenomenon.

Acknowledgements

We wish to thank the Goldstone Research Unit at the University of Pennsylvania for financial support, Werner Güth, Jonathon Baron, Robert Sugden, and seminar participants at the ??Workshop on Social Norms?? and at the Universities of Michigan, CUNY, Yale, Milano, British Columbia, Alabama, Duke, Madrid, Texas at Austin, Arizona and the Wharton School for many useful comments and suggestions. Appendix A: Statistical Methods

Rationale for ~~Statistical Methods~~

Deleted: Using Resampling Methods and Random Effects

To evaluate our hypotheses and predictions, traditional approaches using the general linear model or the chi-square test for independence are inadequate for at least two reasons. Firstly, our data contain multiple responses from each participant. If these responses were substantially correlated, the standard error estimates produced by traditional methods would be too small. Secondly, four of the eighteen cells (3 choices x 3 information conditions x 2 salience treatments) in our data had counts of less than five, making inference based on asymptotic results inadvisable.

The Bootstrap

Asymptotically, logit coefficients and the LRT follow known distributions (under general regularity conditions). However, this is not true for small samples. The bootstrap distribution of a statistic can be used to check the validity of basing inference on asymptotic results. Roughly half of the coefficients in the multinomial logit models we estimated had right-skew (and hence, non-normal) bootstrap distributions, and the majority of the bootstrap distributions of the LRTs were not chi-square. Had we relied on traditional analyses based on the normal and chi-square distributions, our standard error estimates and p-values would have been too small. We provide details of our bootstrap methods below.

Let $y_{\text{obs}} = (y_1, y_2, \dots, y_n)$ denote the vector of observed data, let $T(y_{\text{obs}})$ denote the *statistic* of interest, and let F denote the underlying distribution that generated the data. The bootstrap estimates F using y_{obs} , thereby producing an estimate, F^\wedge , of the distribution of $T(y_{\text{obs}})$. The *non-parametric bootstrap* estimates F^\wedge as the distribution

generated by random sampling with replacement from the set of observed data points, $\{y_1, y_2, \dots, y_n\}$. The *parametric bootstrap* estimates F^\wedge by estimating the model's free parameters and then sampling from the assumed distribution conditional on its parameters being fixed at their estimated values. Using either nonparametric or parametric bootstrap, one generates a bootstrap data set, y , by taking n draws from F^\wedge . The quantity $T(y)$ is the *bootstrap estimate* of $T(y_{\text{obs}})$, and the distribution of $T(y)$ is its *bootstrap distribution*. Letting y_1, y_2, \dots, y_n be n bootstrap data sets, the standard error estimate of $T(y_{\text{obs}})$ is the standard deviation of $T(y_1), T(y_2), \dots, T(y_n)$.

We produced each parametric bootstrap estimate based on the multinomial logit model by 1) fitting the multinomial logit model using maximum likelihood, 2) generating 159 draws from the multinomial distribution with its parameters fixed at their maximum likelihood estimates from step 1, and 3) computing and recording the bootstrap estimates of the statistic of interest. We then repeated the above steps 9,999 times to determine the distribution of the statistic. The procedure for generating non-parametric bootstrap estimates is similar: 1) randomly select 25 Proposers in the control and 28 Proposers in the salient condition, with replacement, 2) compute the statistic of interest, and 3) repeat the previous two steps 9,999 times.

To determine the p-value for each multinomial logit coefficient, we computed the smallest value of α for which zero was not contained in the confidence interval formed by the $(n * \alpha / 2)$ th and $(n * (1 - \alpha / 2))$ th quantiles (sorted values) of the parametric bootstrap estimates of the coefficients, $T(y_1), T(y_2), \dots, T(y_n)$.^{§§} The estimate of the p-value is the proportion of bootstrap estimates that fell strictly outside this

Deleted: P-values Based on Bootstrap Quantiles¶

^{§§} The decimal precision of this value is determined by the number of bootstrap replicates.

interval, which estimates the probability of drawing a coefficient more extreme in either tail of its distribution than the observed value. Although the distribution of the coefficient divided by its estimated standard error converges in probability to the standard normal, this is not necessary true for small samples. Thus, computing a p-value based on quantiles of the bootstrap distribution is preferable. We determined the p-value for the LRT in the same way, except that we constructed a one-sided confidence interval by omitting the division of α by two, as we expected LRTs to be positive under the null hypothesis.

We also used the bootstrap to generate p-values for our hypothesis tests. For our first three hypotheses, we formed our test statistics by taking the predicted probability for the choice and information condition of interest, and subtracting from it the maximum of the predicted probabilities for the two other information conditions. For example, for the first hypothesis, that coin choices would be more likely in the full information condition than in the private or limited conditions, we subtract the maximum of the predicted probabilities of coin in the private and limited conditions from the predicted probability of coin in the full information condition. Because we expected this test statistic to be positive, the p-value was the proportion of bootstrap replicates that were negative. Test statistics for the last three hypotheses were formed analogously.

Deleted: Hypothesis Tests¶

The multinomial logit model produced predicted probabilities, $\hat{\pi}_{(x,y,z)}$, for the 18 cells corresponding to choices, information, and salience ($3 \times 3 \times 2 = 18$). We formed test statistics for our nine hypotheses by taking differences in predicted probabilities. For example, the test statistic for (1) is $\hat{\pi}_{(\text{coin, full, c})} - \max(\hat{\pi}_{(\text{coin, private, c})}, \hat{\pi}_{(\text{coin, limited, c})})$.

Deleted: is

Deleted: Simultaneous Coverage Regions ¶

If we calculated p-values separately for hypotheses (1)-(9), the tests would be valid individually but not simultaneously. Instead, we adjust the p-values for the multiple tests using Buja & Rolke's (2006) method of calibration for simultaneity. For a given test, let α be the smallest value for which the $(N * \alpha)$ th sorted bootstrap estimate lies above zero. The adjusted p-value for that test, p_{adj} , is the proportion of bootstrap data sets in which all nine values simultaneously lie above their respective $(N * \alpha)$ th quantiles. Thus, the statement "The probability of observing a negative difference score under the null hypothesis is p_{adj} ," is true simultaneously for all nine tests.

Appendix B: Proposal Forms

Proposal form for the first game (full information condition)

Proposal form for third game (limited information condition)

<p>(1) Identification number (Proposer fills this out): _____</p> <p>(2) Paired with (Proposer fills this out): _____</p>

(3) Proposer's choices (Proposer check one):

\$5 for Proposer and \$5 for Responder

\$8 for Proposer and \$2 for Responder

Let a coin flip decide which of the above choices will be made.

(4) Responder's decision (Responder check one):

Accept

Reject

Appendix C: Questionnaire 1 for Responders

Item (3) of each block of questions was omitted for the private condition, because Responders did not know that the Coin option was available to Proposers.

Questionnaire

Your identification number: _____

Please guess how many Proposers will choose:

- (1) \$5 for Proposer and \$5 for Responder: _____
- (2) \$8 for Proposer and \$2 for Responder: _____
- (3) Let a coin flip decide: _____

If your guess is correct, you will earn a \$1 bonus.

Please mark any options you believe are fair options. You are free to choose none of the options, one, or more than one option. Your answer will not affect your payment.

- (1) \$5 for Proposer and \$5 for Responder []
- (2) \$8 for Proposer and \$2 for Responder []
- (3) Let a coin flip decide []

Appendix D: Questionnaire 2 for Responders

Please guess how many Responders (excluding you) will select each of the options in the above question as fair options. For each line on which your guess is correct, you will earn a \$1 bonus.

- (1) \$5 for Proposer and \$5 for Responder _____
- (2) \$8 for Proposer and \$2 for Responder _____
- (3) Let a coin flip decide _____

Appendix E: Questionnaire for Proposers

The questionnaire item regarding the Coin option was omitted in the private condition, as Proposers understood that Responders thought the Coin option was unavailable in that condition.

Questionnaire

Your identification number: _____

Each Responder was asked to decide whether the '\$5 and \$5' option is fair.

Please guess how many Responders selected this option as fair: _____

Each Responder was asked to decide whether the '\$8 and \$2' option is fair.

Please guess how many Responders selected this option as fair: _____

Each Responder was asked to decide whether the coin flip option is fair.

Please guess how many Responders selected this option as fair: _____

Note that Responders may answer no to all questions or yes to one or more questions.

For each line on which your guess is correct, you will earn a \$1 bonus.

Table 2. Multinomial logit model of information and salience as predictors of choices.

Maximum likelihood (ML) and bootstrap standard error estimates are included. P-values are based on bootstrap quantiles (see Appendix A for details). The reference level for choice is Coin, for information is the full condition, and for salience is the salient condition.^{†††}

	Log-odds	ML SE	Bootstrap SE	p
(5,5)				
Intercept	0.02	0.37	0.39	.963
Limited	1.84	0.69	1.72	.0007
Private	1.50	0.55	0.72	.0009
Non-Salient	-0.07	0.48	0.48	.913
(8,2)				
Intercept	-0.89	0.45	0.47	.0380
Limited	2.83	0.71	1.73	.0001
Private	1.66	0.59	0.76	.0011
Non-Salient	0.86	0.50	0.53	.0777

^{†††} Thus, for example, the predicted probability of choosing (5,5) in the limited condition and salient treatment is $\exp(.02+1.84)/(\exp(0) + \exp(.02+1.84) + \exp(-.89+2.83)) = .45$.

Deleted: 4

Deleted: 6

Figure 6. Predicted probability of Coin as a function of the Proposer's belief about Responders' normative expectations by condition. The other beliefs are held fixed at their median values.

Deleted: 7

We summarize our predictions below. Let $\pi_{\{x, y, z\}}$ denote the proportion of choice x in information condition y and salience treatment z .

Hypotheses (1) – (6). Choice proportions follow a social norm in which (5,5) and coin are viewed as fair, but (8,2) is not, for both the control and salient conditions:

$$\pi_{\{\text{coin, full, control}\}} > \max(\pi_{\{\text{coin, private, control}\}}, \pi_{\{\text{coin, limited, control}\}}) \quad (1)$$

$$\pi_{\{\text{coin, full, salient}\}} > \max(\pi_{\{\text{coin, private, salient}\}}, \pi_{\{\text{coin, limited, salient}\}}) \quad (2)$$

$$\pi_{\{(5,5), \text{private, control}\}} > \max(\pi_{\{(5,5), \text{full, control}\}}, \pi_{\{(5,5), \text{limited, control}\}}) \quad (3)$$

$$\pi_{\{(5,5), \text{private, salient}\}} > \max(\pi_{\{(5,5), \text{full, salient}\}}, \pi_{\{(5,5), \text{limited, salient}\}}) \quad (4)$$

$$\pi_{\{(8,2), \text{limited, control}\}} > \max(\pi_{\{(8,2), \text{private, control}\}}, \pi_{\{(8,2), \text{full, control}\}}) \quad (5)$$

$$\pi_{\{(8,2), \text{limited, salient}\}} > \max(\pi_{\{(8,2), \text{private, salient}\}}, \pi_{\{(8,2), \text{full, salient}\}}) \quad (6)$$

Hypotheses (7) – (9). Choice proportions reflect normative focus in salient vs. control sessions:

$$\pi_{\{\text{coin, full, salient}\}} > \pi_{\{\text{coin, full, control}\}} \quad (7)$$

$$\pi_{\{(8,2), \text{limited, control}\}} > \pi_{\{(8,2), \text{limited, salient}\}} \quad (8)$$

$$\pi_{\{(5,5), \text{private, salient}\}} > \pi_{\{(5,5), \text{private, control}\}} \quad (9)$$

Table 1. Choices by Information x Salience. Percentages and fractions correspond to each row in the table. S stands for the salient condition, N for non-salient condition, and T for the total.
