# An Easy Case of Sorting by Reversals

Nicholas Tran\*

## Abstract

We show that sorting by reversals can be performed in polynomial time when the number of breakpoints is twice the distance.

## 1 Introduction

A *permutation*  $\pi = (\pi_1 \pi_2 \dots \pi_n)$  is a 1-1 function  $\pi : [0, n + 1] \mapsto [0, n + 1]$ , where  $\pi(0) = 0$ ,  $\pi(n + 1) = n + 1$ , and  $\pi(i) = \pi_i$  for  $1 \leq i \leq n$ . A *reversal of interval*  $[i, j]$  is the permutation

$$\rho_{ij} = (1 \ 2 \ \dots \ i \ j \ j - 1 \ \dots \ i + 2 \ i + 1 \ j + 1 \ j + 2 \ \dots \ n).$$

Given permutations  $\pi$  and  $\sigma$ , the *reversal distance between  $\pi$  and  $\sigma$*  is the length of a shortest sequence of reversals  $\rho_1, \rho_2, \dots, \rho_k$  such that  $\pi \cdot \rho_1 \cdot \rho_2 \cdots \rho_k = \sigma$ . (Note that this definition is robust since the reversals generate the permutation group  $S_n$ .) It is easy to see that this distance is at most  $n - 1$  [WEHM82]. *Sorting by reversals* is the problem of finding the reversal distance  $d(\pi)$  between a permutation  $\pi$  and the identity permutation  $\iota$ .

Fix a permutation  $\pi \in S_n$ . For  $0 \leq i \leq n$ , we call  $(\pi_i, \pi_{i+1})$  an *adjacency* of  $\pi$  if  $\pi_i \sim \pi_{i+1}$  ( $i \sim j$  means  $|i - j| = 1$ ); otherwise,  $(\pi_i, \pi_{i+1})$  is called a *breakpoint* of  $\pi$ . Let  $bp(\pi)$  denote the number of breakpoints of  $\pi$ ; note that  $bp(\pi) \leq n + 1$ , and  $bp(\iota) = 0$ . Two breakpoints of  $\pi$   $(\pi_i, \pi_{i+1})$  and  $(\pi_j, \pi_{j+1})$  define an *active interval*  $[i, j]$  if  $\pi_i \sim \pi_j$  and  $\pi_{i+1} \sim \pi_{j+1}$ ; similarly they define a *passive interval*  $]i, j[$  if  $\pi_i \sim \pi_{j+1}$  and  $\pi_{i+1} \sim \pi_j$ .

Let  $B_\pi$  be the graph whose vertices are breakpoints of  $\pi$ , and whose edges connect those breakpoints that form active or passive intervals. If  $B_\pi$  has a perfect matching  $M$ , let  $I_M$  be the graph whose vertices are the intervals defined by the edges of  $M$ , and whose edges connect intersecting intervals. Two intervals  $[i, j]$  and  $[k, l]$  *intersect* each other if  $i < k < j < l$  or  $k < i < l < j$ .

Currently it is not known whether sorting by reversals can be solved in polynomial time. In fact, the complexity of a weaker question is not known: “Is  $d(\pi) \leq bp(\pi)/2$ ?”

\*Department of Computer and Information Science, University of Pennsylvania, Philadelphia, PA 19104, [nick@central.cis.upenn.edu](mailto:nick@central.cis.upenn.edu)

[KS95, PW95, VP93]. In this paper, we show that the latter problem can be solved in polynomial time.

## 2 Main Result

We begin with an observation about permutations  $\pi$  that satisfy the relation  $d(\pi) = bp(\pi)/2$ .

**Lemma 1** *Let  $\pi \in S_n$  satisfy  $bp(\pi) = 2d(\pi)$ , and suppose  $\pi \cdot \rho_1 \cdot \rho_2 \cdots \rho_{d(\pi)} = \iota$ . Each reversal  $\rho_i$  can be identified with a unique interval of  $\pi$ .*

**Proof:** Since a reversal removes at most two breakpoints, it follows that each  $\rho_i$  removes exactly two breakpoints from  $\pi \cdot \rho_1 \cdots \rho_{i-1}$ . Thus  $\rho_1$  reverses an active interval of  $\pi$ ; identify  $\rho_1$  with this interval. Furthermore, since  $\rho_1$  does not create new intervals and can only change a remaining active interval to a passive interval and vice-versa, each interval of  $\pi \cdot \rho_1$  is an interval of  $\pi$ . We also have  $2d(\pi \cdot \rho_1) = bp(\pi \cdot \rho_1)$  and hence by the induction hypothesis, each  $\rho_2, \dots, \rho_{d(\pi)}$  is identified uniquely with an interval of  $\pi \cdot \rho_1$ , which is different from the one identified with  $\rho_1$ . ■

From the lemma above, we can represent each solution  $\rho_1, \dots, \rho_{d(\pi)}$  by a sequence of intervals corresponding to the  $d(\pi)$  pairs of breakpoints of  $\pi$ .

**Lemma 2** *Let  $\pi \in S_n$  and suppose  $B_\pi$  has a perfect matching  $M$  that has no edges of the type  $]i, i + 2[$ . Then for every interval  $[i, j]$  and  $]k, l[$  of  $\pi$ ,  $[i, j]$  and  $[i + 1, j + 1]$  cannot be both edges of  $M$ , and  $]k, l[$  and  $]k + 1, l - 1[$  cannot be both edges of  $M$ . Thus, if  $(\pi_i = x, \pi_{i+1})$  and  $(\pi_j = x + 1, \pi_{j+1})$  are breakpoints of  $\pi$ , then  $M$  contains exactly one of  $[i, j]$ ,  $]i, j - 1[$ ,  $[i - 1, j - 1]$ ,  $]i - 1, j[$ .*

**Proof:** Suppose to the contrary that  $M$  contains such forbidden pairs of intervals. Associate with each forbidden active pair the value  $v_{i,j} = \max(\pi_{i+1}, \pi_{j+1})$  and each forbidden passive pair the value  $v_{k,l} = \max(\pi_k, \pi_{l+1})$ . Let  $[a, b]$  or  $]a, b[$  be such that  $v_{a,b}$  is maximum. Without loss of generality, say  $v_{a,b} = \pi_a$ . Since  $\pi_a \leq n$ , consider  $\pi_a + 1 = \pi_c$  for some  $c$ . If  $(\pi_{c-1}, \pi_c)$  and  $(\pi_c, \pi_{c+1})$  are two breakpoints of  $\pi$ , then since  $M$  is a perfect matching, it must contain another forbidden pair  $[c - 1, d]$  and  $[c, d + 1]$ , or  $]c - 1, d[$  and  $]c, d - 1[$  for some  $d$ , whose value is  $\pi_a + 2$ , contradicting our choice of  $v_{a,b}$ .

Else exactly one of  $(\pi_{c-1}, \pi_c)$  and  $(\pi_c, \pi_{c+1})$  is a breakpoint of  $\pi$ . Without loss of generality, say  $(\pi_{c-1}, \pi_c)$ . By assumption  $]c, c + 1[$  cannot be an edge in  $M$ , and since  $M$  is a matching, it does not contain an edge of the form  $[a - 1, c - 1]$  or  $[c - 1, a - 1]$  or  $]a, c - 1[$  or  $]c - 1, a[$ . Hence  $M$  has no intervals with  $c - 1$  as an endpoint, contradicting the assumption that  $M$  is a perfect matching. ■

We now characterize those permutations  $\pi$  that satisfy  $2d(\pi) = bp(\pi)$ .

**Theorem 1** *Let  $\pi \in S_n$ . Then  $2d(\pi) = bp(\pi)$  iff there exists a perfect matching  $M$  of  $B_\pi$  such that each connected component of the graph  $I_M$  includes one active interval of  $\pi$ .*

**Proof:** Let  $\rho_1, \dots, \rho_{d(\pi)}$  be a shortest sequence of reversals reducing  $\pi$  to  $\iota$ . Then by the lemma above, each reversal can be identified with a unique interval of  $\pi$ . Representing each reversal as an edge of  $B_\pi$  we obtain a subgraph  $M$  of  $d(\pi)$  edges. Furthermore, no two edges share a vertex since a breakpoint cannot be removed twice. Hence the subgraph  $M$  is a perfect matching of  $B_\pi$ . Finally, note that a reversal can affect only reversals in its connected component of  $I_M$ . Hence, the first reversal of each connected component reverses an active interval of  $\pi$ .

Conversely, suppose  $B_\pi$  has a perfect matching  $M$  such that each connected component of the graph  $I_M$  includes one active interval of  $\pi$ . In particular,  $M$  has no intervals of the type  $]i, i + 2[$ , i.e. the condition of Lemma 2 is met. We show by induction on  $bp(\pi)$  (which must be even since  $B_\pi$  has a perfect matching) that  $2d(\pi) = bp(\pi)$ .

When  $bp(\pi) = 2$ , we have  $d(\pi) = 1$ . Suppose the claim is true for  $n \geq 2$ , and let  $\pi$  be a permutation such that  $bp(\pi) = n + 2$  and  $\pi$  satisfies the condition of this theorem. Let  $M$  be a matching of  $B_\pi$ . Select an active interval  $[i, j]$  among the edges of  $M$  such that the permutation  $\sigma = \pi \cdot \rho_{ij}$  obtained by reversing the interval  $[i, j]$  of  $\pi$  has the most active intervals. If we can show that  $\sigma$  also satisfies the condition of this theorem then by the induction hypothesis  $2d(\sigma) = bp(\sigma)$  and hence  $2d(\pi) \leq 2(d(\sigma) + 1) = bp(\sigma) + 2 = bp(\pi)$ .

First it is clear that the matching  $M$  minus the edge  $[i, j]$  is a perfect matching of  $B_\sigma$ , since the reversal  $[i, j]$  does not destroy other reversals which do not share one of its breakpoints. Call this matching  $N$ . It remains to show each connected component of the graph  $I_N$  has an active interval. Each such connected component is either a connected component of  $I_M$  (and thus has an active interval unaffected by the reversal of  $[i, j]$ ) or a fragment of the connected component  $C_{ij}$  of  $I_M$  that includes  $[i, j]$ . A connected component of the second type must have an interval  $[k, l]$  or  $]k, l[$  intersecting  $[i, j]$ . If this interval is passive in  $I_M$ , it becomes active in  $I_N$  and we are done. Similarly, if in  $I_M$  this interval intersects with an active interval which does not intersect  $[i, j]$ , or if in  $I_M$  it does not intersect with a passive interval which intersects  $[i, j]$ , then in  $I_N$  the interval intersects with an active interval, and we are done.

Thus, suppose in  $I_M$  i) the interval  $[k, l]$  is active and intersects  $[i, j]$ , ii) each active interval intersecting  $[k, l]$  also intersects  $[i, j]$ , and iii) each passive interval intersecting  $[i, j]$  also intersects  $[k, l]$ . From these conditions and the choice of  $[i, j]$ , it follows that any interval (active or passive) intersecting  $[i, j]$  also intersects  $[k, l]$  and vice-versa. Without loss of generality, assume  $i < k < j < l$ . Let  $v = \pi_r$  be the largest integer among  $\pi_{i+1}, \pi_{i+2}, \dots, \pi_k$ , and  $\pi_{j+1}, \pi_{j+2}, \dots, \pi_l$ . Clearly  $v \leq n$ , and so  $v + 1 = \pi_s$  for some  $s$ . By Lemma 2,  $M$  includes exactly one of  $[r, s], ]r, s - 1[, [r - 1, s - 1], ]r - 1, s[$ . This interval cannot intersect both  $[i, j]$  and  $[k, l]$ , contradicting the assumption at the beginning of this paragraph.

Thus we conclude every connected component of  $I_N$  has an active interval, and the theorem follows. ■

**Theorem 2** *Deciding whether  $bp(\pi) = 2d(\pi)$  for any permutation  $\pi \in S_n$  is in  $P$ .*

**Proof:** Given  $\pi$ , we construct the graph  $B_\pi$  and assign to each active interval the weight  $+1$  and each passive interval the weight  $-1$ . Then find a perfect matching  $M$  that has maximum weight. If  $M$  satisfies the condition of Theorem 1 then  $2d(\pi) = bp(\pi)$ . Suppose  $I_M$  has a connected component  $C$  consisting of only passive intervals. Let  $]i, x[$  and  $]y, j[$  be the leftmost and rightmost intervals of  $C$ , respectively. It is clear that every breakpoint between  $i$  and  $j$  is an endpoint of some interval in  $C$ ; otherwise, let  $(\pi_z, \pi_{z+1})$  be such a breakpoint such that  $max(\pi_z, \pi_{z+1})$  is maximum. Then  $C$  must contain an interval  $]z, z'[$  and  $z' > j$  or  $]z', z'[$  and  $z' < i$ , contradicting our choice of  $i$  and  $j$ .

So  $\pi_{i+1}, \pi_{i+2}, \dots, \pi_j$  form a set of consecutive integers  $R$ . If  $B_\pi$  has another perfect matching  $M'$  that satisfies the condition of Theorem 2, then it must have a connected component  $C'$  whose intervals are pairs of breakpoints between  $i$  and  $j$ . Furthermore,  $C'$  has at least one active interval.

Hence we can construct from  $M$  and  $M'$  a new matching  $N'$  by replacing the connected component  $C$  of  $M$  with  $C'$  of  $M'$ . But the weight of  $N'$  is greater than that of  $M$ , a contradiction. Hence  $2d(\pi) \neq bp(\pi)$ . ■
