# Branching Ratio of $^{18}\text{Ne}(7.06 \text{ MeV}, 4^+)$

## Abstract

The recently reported branching ratio (BR) for the  $4^+$  state in  $^{18}\text{Ne}$  at  $E_x = 7.06 \text{ MeV}$  strongly disagrees with the BR computed using the known properties of this state.

There appears to be a serious problem with at least one of the proton branching ratios (BR's) recently reported [1] for astrophysically interesting states near 5–8 MeV in  $^{18}\text{Ne}$ . Almaraz-Calderon *et al.* [1] populated these states with the  $^{16}\text{O}(^3\text{He},n)$  reaction and detected the decay protons. Their reported BR's for the  $4^+$  state at 7.06(10) MeV are listed in Table I. At temperatures above about  $T_9 \sim 2$ , this resonance is the most important for the reaction  $^{14}\text{O}(\alpha, p)$ . Yet the proton branching ratios are in some considerable disagreement. Sometimes the cross section for the reaction  $^{14}\text{O}(\alpha, p)$  is obtained by applying detailed balance to a measured cross section for the time-reversed reaction  $^{17}\text{F}(p, \alpha)$ . The presence of  $p_1$  decays invalidates that procedure.

Harss *et al.* [2] initially assigned  $1^-$  to a state at 7.16(15). We proved it was  $4^+$  [3]. They later agreed [4] and gave  $E_x = 7.05(10)$ . Our calculated energy and alpha width were 7.086(40) MeV [5] and 22.6(3.2) eV [6]. This state should not have a measureable  $p_1$  decay for reasons I now discuss. The largest component in the structure of this state [7] (see Table II) is a collective excitation that is primarily of a four-particle two-hole ( $4p-2h$ ) configuration, i.e.,  $(sd)^4(1p)^{-2}$ , where the  $(sd)^4$  part is basically the first  $4^+$  state of  $^{20}\text{Ne}$ . By use of mirror correspondence, we had earlier calculated the expected energy and proton and alpha widths [3,5,6]. They are listed in Table III. The problem with the new BR is the reported branch to the  $1/2^+$  excited state of  $^{17}\text{F}$ . In order for a  $4^+$  state to decay to  $1/2^+$ , the  $\ell$  value must be 4. This  $4^+$  state is very unlikely to have any appreciable  $g_{9/2}$  strength. Furthermore, because of the large centrifugal barrier the maximum  $\ell = 4$  width is very small. With standard parameters  $r_0 = 1.26$ ,  $a = 0.60$ ,  $r_{0c} = 1.40$  (all in fm), I get  $\Gamma_{\text{sp}}(\ell = 4) = 0.68 \text{ keV}$  for  $4^+$  to  $1/2^+$ . But, the actual situation is even worse. The  $g_{9/2}$  spectroscopic factor is almost certainly no larger than about 0.01–0.02, so the expected width for  $p_1$  decay is  $\Gamma_{\text{calc}} = S\Gamma_{\text{sp}} < 14 \text{ eV}$ . The  $1/2^+$ /g.s. BR, with my calculated ground-state width, is thus less than about  $2 \times 10^{-4}$ , to be compared with the recently reported value [1] of  $0.19 = 0.16(7)/0.83(3)$  for this state. The present value is compared with others in Table IV. I can only conclude that the  $p_1$  decays must be from a nearby state—perhaps the one

TABLE I. Branching ratios from Ref. [1] for the  $4_2^+$  state of  $^{18}\text{Ne}$ .

$E_x$ (MeV)	$J^\pi$	$p_0$	$p_1$
7.06(4)	$4^+$	0.83(3)	0.16(7)

TABLE II. Wave functions from Ref. [7] for  $^{18}\text{O}/^{18}\text{Ne}(4_2^+)$ .

Configuration	Wave-function amplitude
$d^2$	0.120
$dd'$	−0.392
Coll.	0.912

at 7.37 MeV, about which little is known. The recent paper states that the authors did not observe this state, but it was seen in an earlier ( $^3\text{He},n$ ) study [8] with a cross section of about 3% of that for the  $^{18}\text{Ne}(\text{g.s.})$ . Perhaps it is strong enough in the present experiment to account for the  $p_1$  decays. Or, they might be from a previously unknown state in this region of excitation. Hahn *et al.* [8] reported two states near here—at 7.05 and 7.12 MeV.

If the peak attributed [1] to the decay  $^{18}\text{Ne}(7.06 \text{ MeV}) \rightarrow ^{17}\text{F}(1/2^+)$  arises instead from the decay of some other state to  $^{17}\text{F}(\text{g.s.})$ , Almaraz-Calderon *et al.* [10] indicate that the excitation energy of this other state would be about 6.7 MeV—an energy corresponding to no known state in  $^{18}\text{Ne}$ . As they state, this would “indicate the possibility of a new, previously unobserved state in  $^{18}\text{Ne}$ .” Clearly, more work is needed in this important region of  $^{18}\text{Ne}$ .

I note that the new paper states that Harss *et al.* [4] assigned  $2^+$  to the 7.37-MeV state. But that was a suggestion, not an assignment. Harss *et al.* stated that their data are consistent with any natural-parity  $J^\pi$ , up to some high  $J$ . They suggested  $2^+$  simply because the lowest state of  $^{18}\text{O}$  without an identified mirror was the  $2^+$  state at 8.21 MeV. I will not repeat the argument here, but we proved [6] that the 7.37-MeV state in  $^{18}\text{Ne}$  is not the mirror of the 8.21-MeV state in  $^{18}\text{O}$ . Mirrors of both states remain to be identified.

I note that, with our calculated alpha width of 22.6(3.2) eV for the 7.06-MeV state, our value of the relevant astrophysical strength parameter  $\omega\gamma$  is only 0.56 of the one in common use.

TABLE III. Properties of the  $4_2^+$  state.

Quantity	Exp. [1, 4]	Calc.
$E_x$ (MeV)	7.06(4)	7.086(40) [5]
$\Gamma_\alpha$ (eV)	39(13)	22.6(3.2) [6]
$\Gamma_p$ (keV)	90(40)	64(13) [6]

TABLE IV. Reported branching ratios  $p_1/p_0$  for  $^{18}\text{Ne}(7.06\text{ MeV}, 4^+)$ .

Source	Branching ratio
Harss <i>et al.</i> [4]	$\leq 1/90$
Notani <i>et al.</i> [9]	Large
Almaraz-Calderon <i>et al.</i> [1]	0.19
Present	$2 \times 10^{-4}$

In summary, my calculated  $p_1/p_0$  BR for the 7.06-MeV  $4^+$  state of  $^{18}\text{Ne}$  is less than about  $2 \times 10^{-4}$ , in agreement with an earlier limit of  $\leq 1/90$  from Harss *et al.* [4], but not with the value of 0.19 in a recent report [1]. The value from Notani *et al.* [9] is even larger. Finally, the “best”  $\omega\gamma$  for this resonance is only 0.56 of the value in common use.

I am grateful to S. Almaraz-Calderon for informative correspondence.
